Abstract

1 MW CW 23 MHz RF system of the TRIUMF 520 MeV Cyclotron has been in operation for over 40 years. Continuous development of the RF power amplifiers, the waveguide system and of the measurement and protection devices provides reliable operation and improves the performance of the RF System. In this article, operation and maintenance procedure of this RF system are analyzed and recent as well as future upgrades are being analyzed and discussed. In particular, we discuss the improvements of the transmission line’s VSWR monitor and their effect on the protection of the RF system against RF breakdowns and sparks. We discuss the new version of input circuit that was installed, tested and is currently used in the final stage of RF power amplifier. We analyze various schematics and configurations of the Intermediate Power Amplifier (IPA) to be used in the future. The thermo-condition improvements of the Dee voltage probe’s rectifiers are described.

INTRODUCTION

TRIUMF 520 MeV Cyclotron’s high power RF system consists of three main parts – the 1.8 MW CW RF amplifier, the transmission line (TL) and the resonator [1]. The TL itself is composed of two coaxial lines with wave impedances of 50 and 30 ohm. The second part of the TL has three capacitor stations that match 50 ohm impedance of the TL’s first part with the coupling loop port of the resonator that is at TL’s terminus.

Figure 1: RF System of the 520 MeV cyclotron.

TRANSMISSION LINE RESONATOR OPERATION AND SPARK PROTECTION

Instability in the RF system’s operation appears when there are sparks, electrical breakdowns and multipactor discharge in the resonator. The VSWR monitor is used to protect the RF system. This monitor turns off the RF system, if the reflected power in one of the 12 channels exceeds a specified threshold value. The RF control system analyses the rate of Dee voltage drop, classifies the events and then tries to recover the system. The follow up analysis of where sparks and electrical breakdowns took place is done using an oscilloscope. An example of a typical signal pattern that illustrates a spark inside the resonator is presented in Fig. 2.

Figure 2: Resonator RF signals following a spark, when drive is OFF (yellow – drive amplitude, green – Dee voltage, pink – RF signal, blue – rectified voltage of the reflected signal).

The rate of Dee voltage drop allows to determine, whether this spark happened inside the resonator or inside the TL and how large the spark was. The RF control system has sensors to determine the Dee voltage drop and if zero Dee voltage is detected. If either case is detected the RF control system generates the signal to turn OFF the RF drive and to determine the time when RF system’s recovery should be attempted.

However, if these sensors didn’t respond properly or responded with some delay, the standing beat wave in the TL could reach double amplitude of the original signal (see Fig. 3). As a result, some parts of the TL such as matching capacitors, the water feedthrough or the TL conductors and insulators could be damaged.
In order to improve TL’s reliability, the configuration of the conductors in the area with the highest RF field was modified. A simulation in HFSS determined that the RF field is three times higher near the water feed (ε=81) into the central conductor. As a solution, the compression fitting was moved deeper into the central conductor.

**HIGH POWER RF AMPLIFIER**

The high power RF amplifier is composed of the intermediate power amplifier (IPA), the splitter, four high power amplifiers (PA) and three combiners (see Fig.1). The performance and the stability of the RF system is dependent on the quality of vacuum tubes, the ability of the high power RF capacitors to operate in high RF voltage and on the condition of the DC power supplies.

**PA Tuning, Operation and Development**

Each of the four PAs are composed of two 4CW250,000E tetrodes that operate in push-pull mode. Those amplifiers are designed to operate up to 450 kW CW. In order to increase the life time of these tubes they are operated at a 50% lower power and 10% lower filament current (with respect to the nominal values). As a result the tetrodes’ lifetime is now beyond 135,000 hours.

During the last maintenance period, the PA4 amplifier was upgraded. A new input circuit was installed in order to improve its accessibility and to reduce the downtime involved in troubleshooting as well as during input capacitor replacement.

**IPA Operation, Tuning and Development**

The IPA consists of two stages: a pre-amplifier pentode and a final tetrode. The maximum power that could be reached under the current design is 100 kW. However, in order to increase the life time of the IPA tubes, a 4CW100,000E tetrode is used at the output stage to reach only 50 kW and is operated at 10% lower filament current.

The tetrode stage is loaded with the Pi-network which is connected to the 4-way splitter. This splitter distributes the output power between PAs inputs. To determine the impedance of this load, the method of variations of capacitances [2] was applied to the Pi-network. Independent variations of C37, C40 (see Fig. 7) from the...
original values allow to derive five equations for resonance conditions with $C_{37}$, $C_{40}$ and $L_{19}$ being the unknown variables.

\[
\begin{align*}
\text{Im}(Z_{\text{inp}}(\omega_1, R_{\text{load}}, C_{bl1}, C_{ca}, C_{37}, C_{40}, L_{19})) &= 0 \\
\text{Im}(Z_{\text{inp}}(\omega_2, R_{\text{load}}, C_{bl1}, C_{ca}, C_{37}', C_{40}, L_{19})) &= 0 \\
\text{Im}(Z_{\text{inp}}(\omega_3, R_{\text{load}}, C_{bl1}, C_{ca}, C_{37}, C_{40}', L_{19})) &= 0 \\
C_{37}' &= C_{37} + \Delta C_{37} \\
C_{40}' &= C_{40} + \Delta C_{40}
\end{align*}
\]

where $\omega_1$, $\omega_2$, $\omega_3$, $R_{\text{load}}$, $C_{bl1}$, $C_{ca}$ are the measured values, values of $C_{37}$, $C_{40}$, $L_{19}$ are the unknowns. MathCAD Prime 3.1 has been used to solve this system of equations.

This more precise measurement of load impedance allowed to determine the regime of tubes. As a result, the screen current was reduced, which allowed more stable tube operation.

Currently the IPA is being redesigned. The new IPA configuration will have four independent 12 kW solid state amplifiers directly connected to the inputs of PA amplifiers. The amplitude and the phase will be fixed before each IPA input. The development of a new IPA design will be carried out in several stages. Currently the IPA is based on pentode and tetrode vacuum tubes, where the tetrode has the neutralization circuit via the pentode load. The goal of the first stage of the new design is to make these tubes independent. In the second stage of the new design, the pentode will be replaced by a 2 kW solid state amplifier. In order to achieve independence of the pentode and the tetrode, a different neutralization circuit is proposed for the tetrode (Fig. 8). This circuit has been developed using the prototype that currently is used as a part of TRIUMF’s ISAC-1 particle accelerator. The mechanical design and the series of simulations in Micro-Cap and Altium Designer 10 are currently completed. The equivalent circuit for neutralization and the results of simulation in Micro-Cap presented on Fig. 9. The current timeline is to rebuild and test IPA in the winter shutdown of 2017.

**MAINTENANCE OF RF SYSTEM**

All high power RF components such as vacuum capacitors of the amplifier, combiners and the TL have an annual maintenance service carried out during the 4-month winter shutdown or during the 10 days of the autumn mini shutdown. A hi-pot test for the capacitors and the vacuum tubes, inspection and cleanup of RF components, a low and high power level tuning are carried out during those maintenance periods. An inspection of the TL, the vacuum capacitors of the matching stations, the booster resonator, the water cooling pipes and hoses in the vault are also performed during every winter shutdown.

**CONCLUSION**

Fine tuning of PAs and the IPA, installation of the RF switch in the VSWR monitor, thermo-stabilization of the Dee voltage rectifiers resulted in stable operation of the high power RF system for a period of few months without any major interruptions.
