ANALYTICAL ESTIMATION OF DYNAMIC APERTURES LIMITED BY THE WIGGLERS IN STORAGE RINGS

J. Gao, Laboratoire de L’Accélérateur Linéaire, B.P. 34, 91898, Orsay cedex, France

Abstract

By applying the general dynamic aperture formulae for the multipoles in a storage ring developed in ref. [1] (J. Gao, Nucl. Instr. and Methods A451 (2000), p. 545), in this paper, we give the analytical formulae for the dynamic apertures limited by the wigglers in storage rings.

INTRODUCTION

Wigglers as an insertion device finds many applications in damping rings [2], synchrotron radiation facilities [3] [4], and storage ring colliders [5]. Intrinsically, as a nonlinear device, together with the perturbations to the linear optics it brings additional limitations to the general performance of the machines, such as reducing dynamic apertures. In this paper, we will estimate in an analytical way the dynamic apertures limited by wigglers. Firstly, in section 2, we make a brief review of the beam dynamics inside a wiggler, and secondly, in sections 3 a wiggler is inserted into a storage ring as a perturbation. By applying the general dynamic aperture formulae of multipoles in a storage ring developed in ref. [1], in section 4 we derived analytical formulae of the wiggler limited dynamic aperture. Finally, in section 5 some numerical examples will be given.

PARTICLE’S MOTION INSIDE A WIGGLER

Considering a wiggler of sinusoidal magnetic field variation, one can express the wiggler’s magnetic fields, which satisfies Maxwell equations, as follows:

\[ B_x = \frac{k_x}{k_y} B_0 \sinh(k_x x) \sinh(k_y y) \cos(ks) \]  
\[ B_y = B_0 \cosh(k_x x) \cos(k_y y) \cos(ks) \]  
\[ B_z = -\frac{k}{k_y} B_0 \cosh(k_x x) \sinh(k_y y) \sin(ks) \]  

with

\[ k_x^2 + k_y^2 = k^2 = \left( \frac{2\pi}{\lambda_w} \right)^2 \]  

where \( B_0 \) is the peak sinusoidal wiggler magnetic field, \( \lambda_w \) is the period length of the wiggler, and \( x, y, s \) represent horizontal, vertical, and beam moving directions, respectively.

The Hamiltonian describing particle’s motion can be written as [3]:

\[ H_w = \frac{1}{2} \left( \rho_x \frac{p_x}{\rho_w k} \cosh(k_x x) \cosh(k_y y) - A_x \right)^2 + \left( \rho_y - A_y \sin(ks) \right)^2 \]  

where

\[ A_x = \frac{1}{\rho_w k} \cosh(k_x x) \cosh(k_y y) \]  
\[ A_x = -\frac{k_x}{k_y} \sinh(k_x x) \sinh(k_y y) \rho_w k \]  

and \( \rho_w \) is the radius of curvature of the wiggler peak magnetic field \( B_0 \), and \( \rho_w = E_0/eB_0 \) with \( E_0 \) being the electron energy. After making a canonical transformation to betatron variables, averaging the Hamiltonian over one period of wiggler, and expanding the hyperbolic functions to the fourth order in \( x \) and \( y \), one gets:

\[ H_w = \frac{1}{2} \left( \rho_x^2 + \rho_y^2 \right) \]
\[ + \frac{1}{4k_w^2 \rho_w^2} \left( k_x^2 x^2 + k_y^2 y^2 \right) + \frac{1}{12k_w^2 \rho_w^4} \left( k_x^4 x^4 + k_y^4 y^4 + 3k_x^2 k_y^2 x^2 y^2 \right) \]
\[ - \frac{\sin(ks)}{2k_w \rho_w} \left( \rho_x \left( k_x^2 x^2 + k_y^2 y^2 \right) - 2k_x^2 \rho_y x y \right) \]

After averaging the motion over one wiggler period, one obtains the differential equations for particle’s transverse motions [6]:

\[ \frac{d^2 x}{ds^2} = -\frac{k_x^2}{2k_w^2 \rho_w^2} \left( x + \frac{2}{3} k_x^2 x^3 + k_x^2 x^2 y^2 \right) \]  
\[ \frac{d^2 y}{ds^2} = -\frac{k_y^2}{2k_w^2 \rho_w^2} \left( y + \frac{2}{3} k_y^2 y^3 + k_y^2 x^2 y \right) \]

Considering the wigglers are built with plane poles, one has \( k_x = 0 \).

WIGGLER AS AN INSERTION DEVICE IN A STORAGE RING

Now we insert a “wiggler” of only one period (or one cell) into a storage ring located at \( s_w \). The total Hamiltonian of the ring in the vertical plane can be expressed as Hamiltonian:

\[ H = H_0 + \frac{1}{4\rho^2} \sum_{\lambda_w=-\infty}^{\infty} \delta(s - iL) \]

where \( H_0 \) is the Hamiltonian without the inserted wiggler, \( L \) is the circumference of the ring, and \( k_w = k \). It is obvious that the perturbation is a delta function octupole.

Now, let’s recall some useful results obtained in ref. [1] where we have studied analytically the one dimensional dynamic aperture of a storage ring described by the following Hamiltonian:

\[ H = \frac{p_x^2}{2} + \frac{K(s)}{2} x^2 + \frac{1}{3! B \rho} \frac{\partial^3 B_z}{\partial x^3} \sum_{k=-\infty}^{\infty} \delta(s - kL) \]
\[ + \frac{1}{4l_B \rho} \frac{\partial^3 B_z}{\partial x^3} x^4 L \sum_{k=-\infty}^{\infty} \delta(s - kL) + \cdots \]  

(12)

where

\[ B_z = B_0(1 + x_{b1} + x^2 b_2 + x^3 b_3 + \cdots + x^{m-1} b_{m-1} + \cdots) \]  

(13)

The dynamic aperture corresponding to each multipole is given as:

\[ A_{dyna,2m,x}(s) = \sqrt{2} \frac{\beta_x(s)}{\beta_y(s_w)} \left( \frac{3 \rho_w^2}{k_w^2 \lambda_w} \right)^{1/2} \left( \frac{1}{m \beta_x''(s_{2m})} \right)^{1/2} \]  

(14)

where \( s_{2m} \) is the location of the \( 2m \)th multipole, \( \beta_x(s) \) is the beta function in the \( x \) plane, and \( x \) here stands for either horizontal or vertical plane.

Comparing eq. 11 with eq. 12, by analogy, one finds easily that:

\[ \frac{b_3}{\rho} = \frac{k_w^2 \lambda_w}{3 \rho_w} \]  

(15)

and the dynamic aperture limited by this one period “wigglers”:

\[ A_{1,y}(s) = \sqrt{\frac{\beta_y(s)}{\beta_y(s_w)}} \left( \frac{3 \rho_w^2}{k_w^2 \lambda_w} \right)^{1/2} \]  

(16)

where \( \beta_y(s) \) is the unperturbed beta function. In fact, a wigglers is an insertion device which is composed of a large number, say, \( N_w \), and the wigglers length \( L_w = N_w \lambda_w \). Now, the first question which follows is what the combined effect of these \( N_w \) cells will be. According to ref. [1], one has:

\[ \frac{1}{A_{N_w,y}^2(s)} = \sum_{i=1}^{N_w} \frac{1}{A_{i,y}^2(s)} = \sum_{i=1}^{N_w} \left( \frac{k_w^2}{3 \rho_w^2 \beta_y(s)} \right) \beta_y^2(s_{i,u}) \]  

(17)

where the index \( i \) indicates different cell. When \( N_w \) is a large number, Eq. 17 can be simplified as:

\[ \frac{1}{A_{N_w,y}^2(s)} = \frac{k_w^2}{3 \rho_w^2 \beta_y(s)} \int_{s_{u0} + L_w/2}^{s_{u0} - L_w/2} \beta_y^2(s) ds \]  

(18)

where \( s_{u0} \) correspond to the center of the wigglers. If the variation of the unperturbed beta function inside the wigglers is approximated as linear, one gets

\[ A_{N_w,y}(s) = 3 \sqrt{\frac{\beta_y(s)(\beta_y - \beta_y)}{\beta_y' - \beta_y}} \frac{\rho_w}{k_y \sqrt{L_w}} \]  

(19)

where \( \beta_{y,1} \) and \( \beta_{y,2} \) correspond to the beta function values at the two extremities of the wigglers. As is well known, the inserted wigglers perturbs linear optics also, such as tune shifts and beta functions. In our specific case [7], we have \( \Delta \nu_x = 0, \Delta \beta_x = 0, \) and

\[ \Delta \nu_y \approx \frac{L_w \beta_{av,y}}{8 \pi \rho_w^2} \]  

(20)

where \( \beta_{av,y} \) is the averaged beta function within the wigglers. The fact that the tune shift and the beta function inside the wigglers vary in a complex way makes us assume that the octupole like cells of the wigglers are independent from one to another, and permits us to arrive at the expression in eq. 17.

The second question which follows is how about the total dynamic aperture of the storage ring including many wigglers and other nonlinear components. Assuming that the dynamic aperture of the ring without the wigglers’ effects is \( A_y \) and that there are \( M \) wigglers to be inserted inside the ring at different places, one has the total dynamic aperture expressed as:

\[ A_{total,y}(s) = \frac{1}{\sqrt{\frac{1}{A_y^2(s)} + \sum_{j=1}^{M} \frac{1}{A_{j,w,y}^2(s)}}} \]  

(23)

where \( A_{i,w,y} \) denotes the dynamic aperture limited by the \( j \)th wiggler.

**NUMERICAL EXAMPLE**

Now we take TESLA damping ring for example with permanent magnet wigglers [2], where one has \( E_0 = 5 \mathrm{GeV}, B_0 = 1.68 \mathrm{T}, \lambda_w = 0.4 \mathrm{m}, N_w = 12, \beta_{y,1} = 9 \mathrm{m}, \beta_{y,2} = 15 \mathrm{m}, \) and total wigglers number \( M = 45 \). Without considering the dynamic aperture limited by other nonlinear components, by applying eqs. 19 and 23, one finds that \( A_{total,y}(s_{u0}) = 21 \mathrm{mm} \). Recalling the gap of the wigglers [2], \( g = 25 \mathrm{mm} \). It should be noted that eqs. 19 and 23 correspond to ideal wigglers. If the octupole components of a real wigglers is measured to be a factor of “\( g \)” larger than that of the ideal wigglers, the values of the dynamic apertures of real wigglers should be those evaluated by eqs. 19 and 23 divided by \( \sqrt{g} \).

**CONCLUSION**

In this paper we have developed the analytical dynamic aperture formulae limited by wigglers in storage rings, which are very efficient and powerful in designing and operating damping rings and synchrotron radiation facilities.
