ACCELERATING RF SYSTEM OF MICROTRON-RECUPERATOR FOR FEL

Budker Institute of Nuclear Physics, Lavrentev Avenue, 11 630090 Novosibirsk Russia

Abstract

FEL (Free Electron Laser) for the Siberian Centre of Photochemical Research is constructed in Novosibirsk. Parameters and last results received on a RF system of the race-track microtron-recuperator for FEL are given in the report. The frequency of the RF system is 180.4 MHz. The RF system operates in continuous mode. The 16 cavities are used in accelerating system of the microtron-recuperator. The RF system is consists of two channels. Each of two 600 kW generators drives 8 cavities. Each channel was tested at 7500 kV on the gaps of 8 cavities. The RF power was 630 kW per channel. Now, the accelerating RF system operates at 13600 kV on 16 cavities. Total power of generators is 1100 kW.

INTRODUCTION

Project parameters for accelerating cavities voltage and output power of RF generators of RF system of a race-track microtron-recuperator for free electrons laser (FEL) of the Siberian Centre of Photochemical Research are achieved in the Budker Institute of Nuclear Physics (BINP).

The recuperation is carried out at 13.5 MeV beam energy and at 10 mA beam current (the injector current restriction).

RF SYSTEM

The RF system of the microtron-recuperator (Fig.1) operates on frequency 180.4 MHz at 1.2 MW CW mode.

The RF system consists of 16 cavities. Even and odd cavities are united into two groups. Each group of cavities is fed from its own RF generator. Project power of each RF generator is 600 kW.

Cavities

In the RF system, bi-metal cavities are used (copper - stainless steel). The schematic drawing of cavities is shown on Fig.2.

![Fig.2: Bi-metal cavities](image)

The general view of the cavities is shown on Fig.3.

Generators

Each generator consists of four stages (Fig.4). First and second amplifier stages are made of tetrodes GU-92A. Third and fourth (output) stages are made of modules based on tetrodes GU-101A. Vacuum tubes are made by the company “SED-SPb”, (“Svetlana”), St. Petersburg, Russia.

![Fig.5: RF generator, general view](image)

The modular design of the RF generator (Fig.5) essentially simplifies the power addition from several tubes, and simplifies manufacturing and adjustment of the whole generator. The 600 kW output stage is assembled with four modules. The single module is used as a preamplifier (the third stage of the RF generator).
Feeder System

Feeder system is made of aluminum rectangular waveguides and coaxial lines. The system of power division (Fig.6) is a rectangular waveguide (with cross-section 958x415 mm) connected with cavities by coaxial feeders. Groups of even and odd cavities are connected to the different waveguides.

The control system consists of two identical independent channels. The signals from eight accelerating cavities of the channel come to the amplitude detectors. The sum of the detector outputs is used as a feedback signal that operates the input power of the RF generator.

The phase tuning circuit adjusts the accelerating voltage phase of each channel to a master oscillator phase within the range of 360 degrees.

SUMMARY

Each channel was tested at 7500 kV on the gaps of 8 cavities. The RF power was 630 kW per channel. The efficiency factor of the output stage is 57%.

Now, the accelerating RF system operates at 13600 kV on 16 cavities. Total power of generators is 1100kW.
