Feasibility of Hardware Acceleration in the LHC Orbit Feedback Controller (OFC)

L. Grech, G. Valentino, D. Alves, S. Jackson, J. Wenninger

Abstract: Orbit correction in accelerators typically make use of a linear model of the machine, called the Response Matrix (RM), that relates local beam deflections to position changes. The RM is used to obtain a Pseudo-Inverse (PI), which is used in a feedback configuration, where positional errors from the reference orbit as measured by Beam Position Monitors (BPMs) are used to calculate the required change in the current flowing through the Closed Orbit Dipoles (CODs). The calculation of the PIs from the RMs is a crucial part in the LHC’s Orbit Feedback Controller (OFC), however in the present implementation of the OFC this calculation is omitted as it takes too much time to calculate and thus is unsuitable in a real-time system. As a temporary solution the LHC operators pre-calculate the new PIs outside the OFC, and then manually upload them to the OFC in advance. In this paper we aim to find a solution to this computational bottleneck through hardware acceleration in order to act automatically and as quickly as possible to COD and/or BPM failures by recalculating the PIs within the OFC. These results will eventually be used in the renovation of the OFC for the LHC’s Run 3.

OFC and SVD

- RM is generated from the LHC optics
- RM relates COD deflections to positional vector
- Malfunctions in BPMs and CODs
  - Regenerate RM
  - Recalculate PI

Problem Definition

- During normal LHC operation several RMs are used.
- Different optics, e.g. during RAMP 13-14 RMs are used
- BPM and COD malfunctions prompt regeneration of RM and consecutive PI re-calculation
- Re-calculation of PI for each RM is a computational bottleneck in the OFC

Proposed Solution

- Hardware acceleration to speed-up PI re-computation through SVD
  - ArrayFire → Hardware acceleration library
  - CUDA, OpenCL or optimised CPU implementations of SVD

Results

- Benchmarking test shows that ArrayFire using CPU obtained the best performance

Conclusion

From the work presented in this paper, it was concluded that hardware acceleration libraries offer a good solution to solve the computational bottleneck found in the current implementation of the OFC when it is calculating the pseudo-inverse for the response matrix used between the CODs and the BPMs. However the use of GPUs in future designs of the OFC would not be recommended due to the relatively small matrices used in the calculations. It was found that the time overhead of copying the input matrix to the GPU would balance out the accelerated computation by the GPU. In conclusion the preferred choice for accelerating the SVD computation within the OFC is ArrayFire using CPUs.
