# Polarization Control in High Gain Free Electron Lasers

Eugenio Ferrari

École Polytechnique Fédérale de Lausanne

PSI - Paul Scherrer Institut

## Outline

- Light **polarization** and polarization control in FELs
- Crossed polarized undulator schemes
- **Implementation** of the crossed polarized undulator scheme at FERMI
- **Model** for the experimental results
- Strategies to **improve** the degree of polarization of the output radiation

# Polarization of Light

The **polarization** of the light describes the way in which the electric field of an electromagnetic wave is oscillating.

If the oscillation is along a single direction, the light said to be linearly polarized

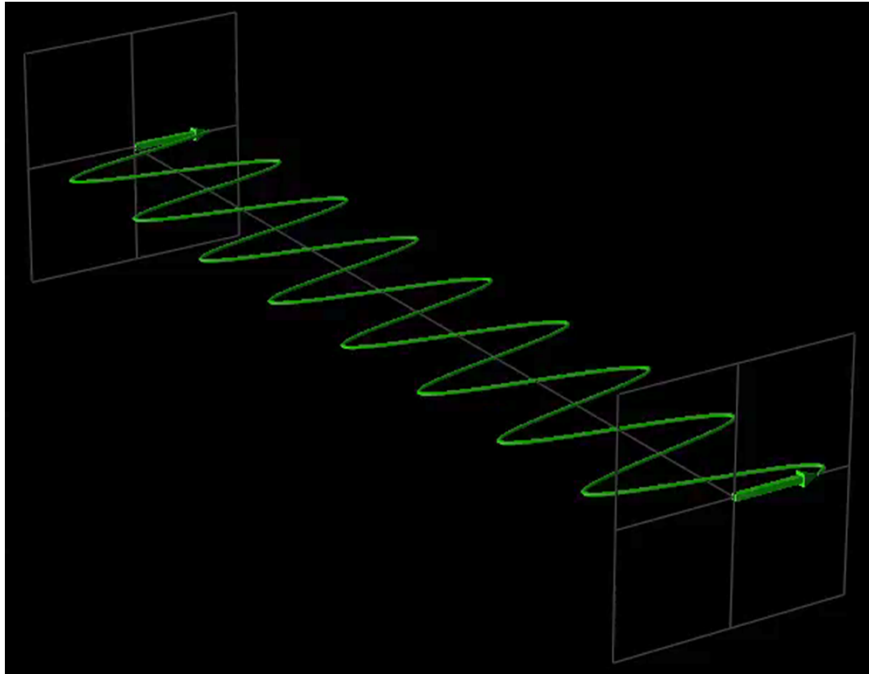

Linear Horizontal

Linear Vertical

Animations from **EMANIM**: <http://www.enzim.hu/~szia/emanim/emanim.htm>

# Polarization of Light

**Polarized light is naturally produced by FEL sources as they utilize undulators.**  
**“Normally” with linear polarization**

# Polarization of Light

If the oscillation of the electric field is rotating, the light has an elliptical or circular polarization.

Circular Left

Circular Right

## Why considering polarized light?

For the Experiments:  
e.g.: dichroic studies

Cobalt film  
(Curtesy C. Spezzani)

Visualization of magnetic domains

For the FEL:

Larger field-electron coupling

E.g., 1D gain length (E.L. Saldin)

$$L_{g0} = 1.67 \left( \frac{I_A}{I} \right)^{1/2} \frac{(\epsilon_n \lambda_w)^{5/6}}{\lambda_r^{2/3}} \frac{(1 + K^2)^{1/3}}{K A_{JJ}}$$

$$A_{JJ} = J_0(K^2/2(1+K^2)) - J_1(K^2/2(1+K^2)) \quad \text{Planar und.}$$

$$A_{JJ} = 1 \quad \text{Helical und.}$$

$$K \sim 2 \rightarrow A_{JJ} \sim 0.75$$

Gain length is ~25% shorter for  
helical undulators.

For SASE machines the typical  
undulator length is ~100 m

# Variable Polarization Undulators for short wavelength, high gain FELs

Delta Undulator

APPLE-II Undulator

Capable of producing linear, circular and elliptical polarized light.  
“Slow” switching between different polarization states

# Delta undulator at LCLS

Installed at girder 33, work as variable polarization “afterburner”  
The ratio between linearly and circularly polarization is about 5  
(20 with reverse taper)

## Cookiebox (DESY)

Frau Merkel approved!

# Polarization stability

The device is capable of measuring the polarization on a **shot-to-shot** basis

Horizontal Polarization

The polarization state in the example is **linear horizontal**.  
The measured stability is dominated by the **statistical fluctuations** on the single e-TOF signals, rather than real fluctuations of the polarization itself

## Polarization control via crossed undulators

Crossed polarized undulators emit radiation with orthogonal polarization between each other (e.g., H+V or CL+CR)

Original idea from Kim:

- synchrotron light (K.-J. Kim, NIM 219, 425 (1984))
- FELs (K.-J. Kim, NIM A 445, 329 (2000))

Image from J. Bahrtdt et. al.,  
Rev. Sci. Instr. 63, 339 (1992)

Critical ingredients: coherent, narrow bandwidth source

## Examples of Crossed Polarization

linear horizontal + linear vertical  
=  
circular left polarization

circular left + circular right  
=  
linear horizontal polarization

## Crossed undulator scheme

Studied with SASE FEL based on FLASH, Eu-XFEL and LCLS setup

A nice working point has been found, **just before saturation**, in order to have as **identical** as possible **emission** from the two crossed undulators.

Image from Y. Li et. al,  
EPAC 08, WEPC118

The **intrinsic spiky** structure and fluctuations of SASE degrade the polarization performances, with a maximum degree of polarization possible of the range **80 – 90%** .

Y. Ding and Z. Huang PR ST-AB **11**, 030702 (2008)

Y. Li et. al, EPAC 08, WEPC118 (2008).

## Crossed undulator scheme

### Seeded FELs:

The properties of the emitted radiation should be the right ones for the crossed polarized scheme, in particular the **longer temporal coherence** and shot-to-shot stability.

Theoretically, a degree of polarization **larger than 90%** is expected.

### Experimentally demonstrated at SDUV FEL.

H. Deng et. al., PR-AB 17, 020704 (2014).

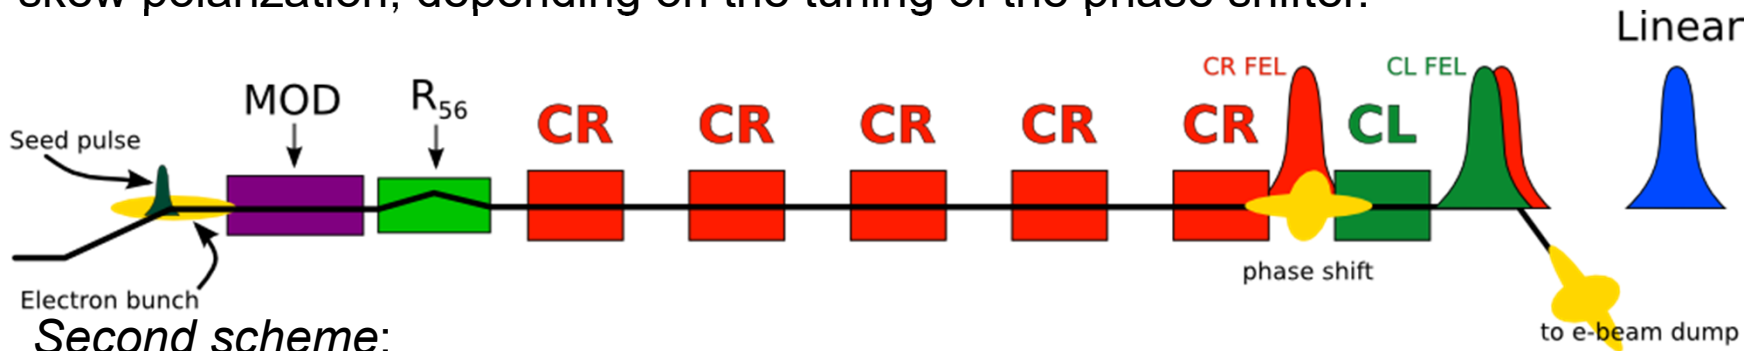

# Implementing cross polarization at FERMI

## First scheme:

The first part of the radiator emits **Horizontal** polarized light, only one radiator produces **Vertical** polarized light, to produce **Circular** polarization or Linear skew polarization, depending on the tuning of the phase shifter.

## Second scheme:

It is also possible, using the elliptically polarized undulators at FERMI, to perform crossed polarization by using **Right Circular** and **Left Circular** light to obtain **Linear** polarization with adjustable polarization direction.

Useful because the Cookiebox is sensitive to linearly polarized light.

## Balancing the emission is critical

If the two sources are not balanced, the emission exhibits elliptical polarization or there could be loss of polarization

# Balancing the emission in presence of gain

It is critical to balance the intensity of the two sources.

Measuring a gain curve, we can change the **seeding parameters** in order to have that the first 5 undulators emit almost the same intensity as the last undulator alone.

**OPEN** Single Shot Polarization Characterization of XUV FEL Pulses from Crossed Polarized Undulators

Received: 22 April 2015  
Accepted: 29 July 2015  
Published: 28 August 2015

E. Ferrari<sup>1,2</sup>, E. Allaria<sup>1</sup>, J. Buck<sup>3</sup>, G. De Ninno<sup>1,4</sup>, B. Diviacco<sup>5</sup>, D. Gauthier<sup>1,4</sup>, L. Giannessi<sup>1,5</sup>, L. Glaser<sup>6</sup>, Z. Huang<sup>7</sup>, M. Ilchen<sup>1,8</sup>, G. Lambert<sup>9</sup>, A.A. Lutman<sup>7</sup>, B. Mahieu<sup>9</sup>, G. Penco<sup>5</sup>, C. Spezzani<sup>1</sup> & J. Viefhaus<sup>6</sup>

The measured degree of linear polarization is 70%, lower than expected (cfr. H. Deng et. al., PR-AB 17, 020704 (2014), 80% obtained)

How to explain the lower degree of  
polarization obtained?

# Interference effects between different sources

Full radiator tuned at the same polarization

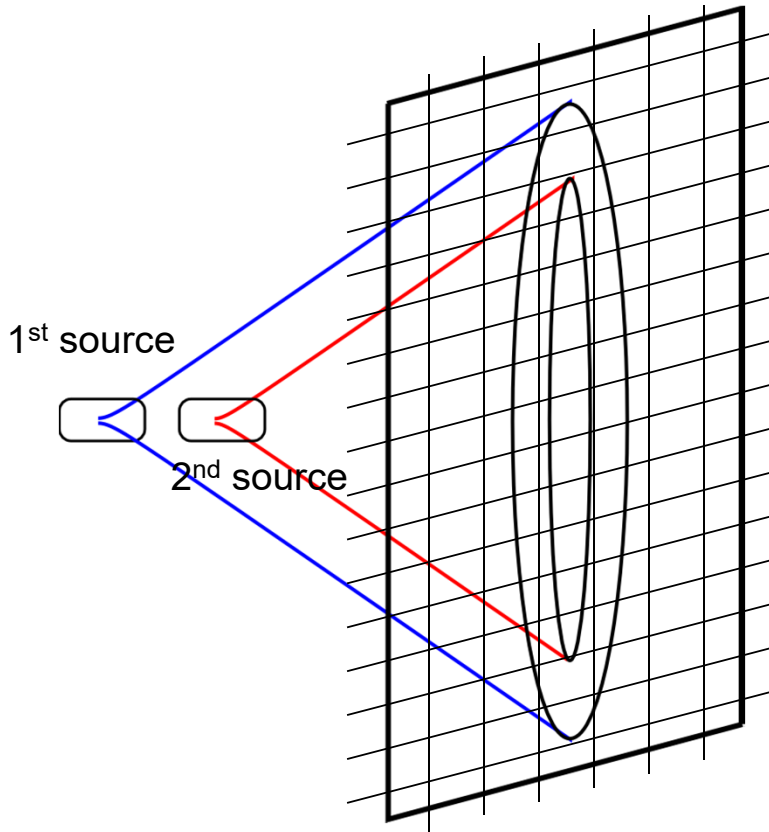

Intensity and FEL transverse mode exhibit interference patterns for different phasing (phase shifter setting) between two undulator groups

## Model: interference of two Gaussian sources

Two or more monochromatic Gaussian beams propagating in free space.

Output: 2D map of the polarization properties of the radiation on a grid.

# Model: interference of two Gaussian sources

## Two sources with orthogonal polarization

Intensity

$P_{lin}$

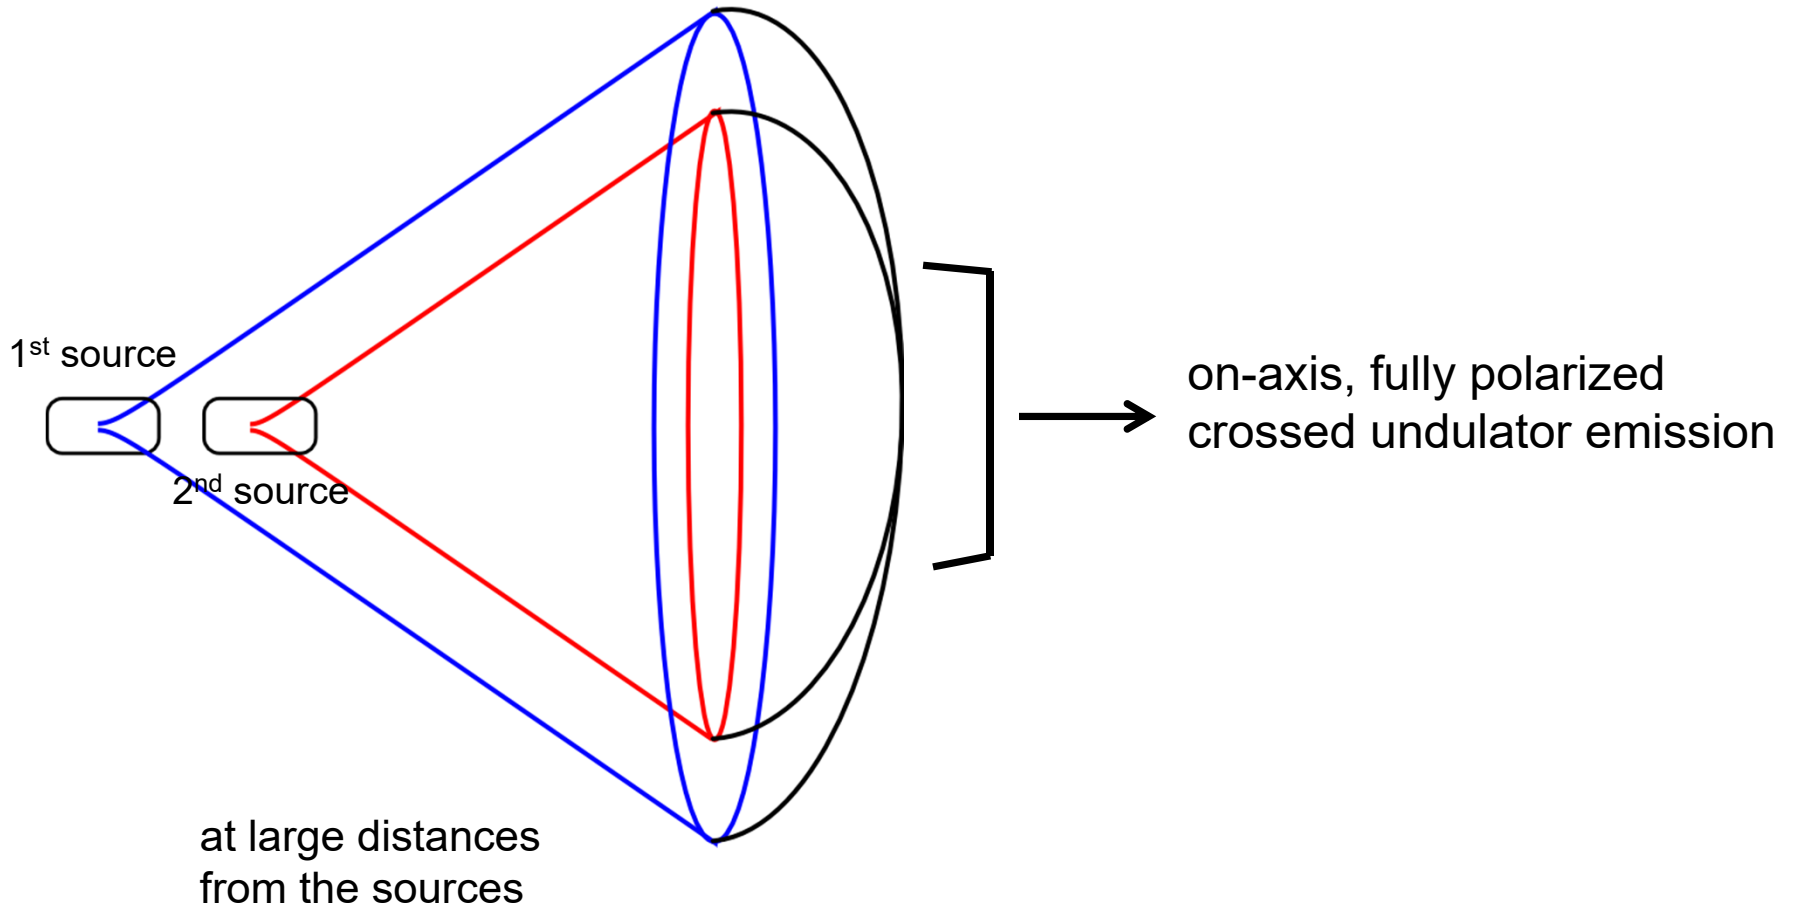

Angle

# Model: interference of two Gaussian sources

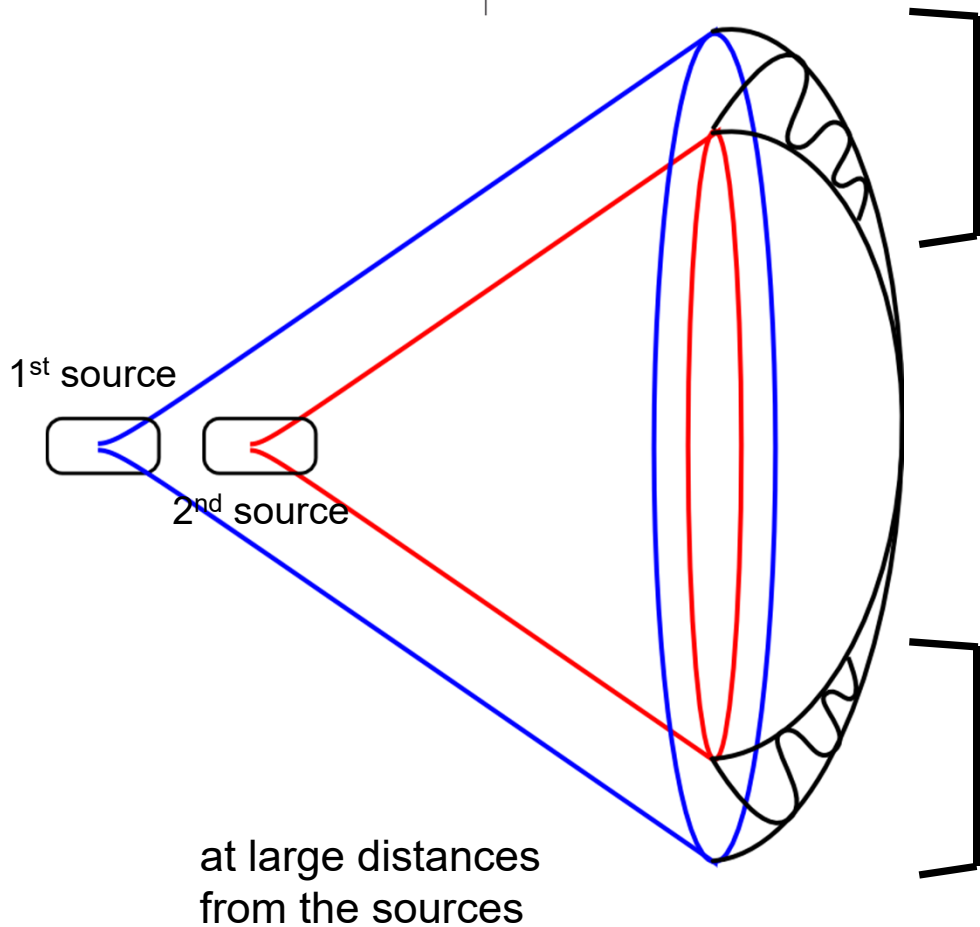

# Model: interference of two Gaussian sources

off-axis, the phase of each of the two sources is not constant. The resulting field has strong phase and intensity variations off-axis, inducing a loss of polarization

# Model: interference of two Gaussian sources

off-axis, the phase of each of the two sources is not constant. The resulting field has strong phase and intensity variations off-axis, inducing a loss of polarization

The ratio of Rayleigh range and source distance is the critical parameter

Summary of the **Rayleigh ranges** and **undulator distances** for different FEL sources implementing the crossed undulator scheme

FEL source	Wavelength	Rayleigh range	Distance Crossed undulators	Max degree of polarization (from Model)
LCLS like	Hard X	~ 100 m	3 – 5 m	> 99 %
SDUV FEL	Visible	~ 1 m	0.5 – 1 m	> 90 %
FERMI FEL1	EUV	~ 1 m	~ 3.5 m	~ 70 %

At FERMI the Rayleigh range can be smaller (wavelength dependence) than the distance between the crossed undulators, so the maximum degree of linear polarization achievable with the crossed scheme is ~70%.

# Measure: Polarization through different apertures

Experimental confirmation  
of the model:  
the polarization state  
changes along the  
transverse FEL profile

Centered aperture statistics

## Distributed crossed polarized scheme

Another approach to improved the polarization

Inspired by the G. Geloni and colleagues idea for the LCLS design ([Shanghai FEL2011](#)), to equilibrate the intensities of the two crossed polarization sources in a SASE.

A similar idea was also proposed by [T. Tanaka](#) and [H. Kitamura](#), *Improvement of crossed undulator for higher degree of polarization*, AIP Conference Proceedings, 705 (2004) 231.

# Distributed scheme

# Crossed Undulators to control the Polarization

# Control of the Polarization Direction

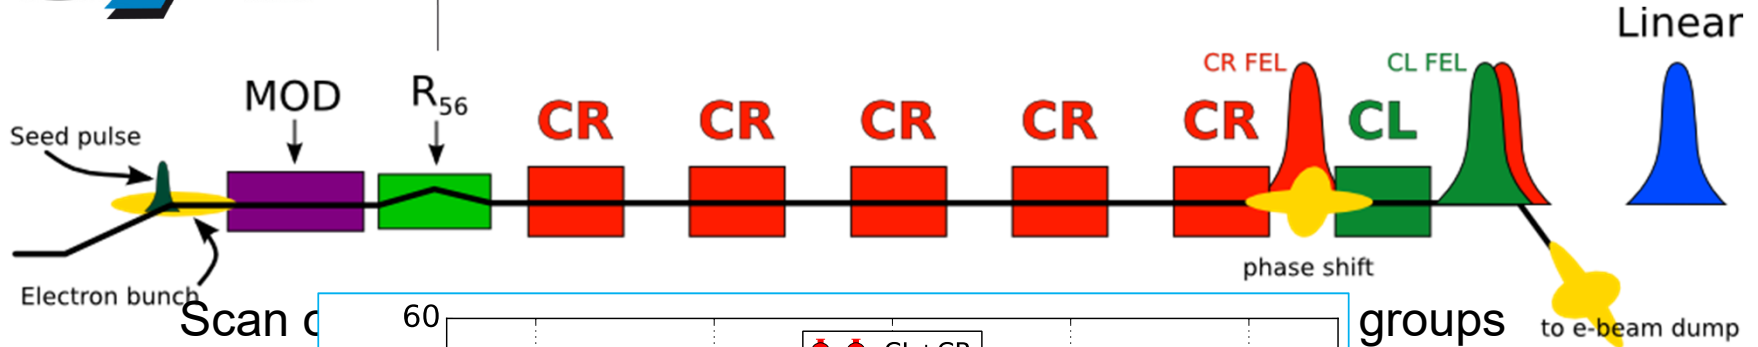

Scan of the phase shifter in between the two undulator groups while recording the polarization

All the FEL shots during the acquisition

The direction of the linear polarization is altered by changing the phase shifter

# Control of the Polarization Direction

The dir... altered by changing the phase shifter

# Linear polarized light without harmonics

Full undulator in linear polarization  
at ~21 nm

Crossed polarized undulators (CR+CL)

Third harmonic signal is **suppressed** and radiation is linearly polarized  
Critical for experiments investigating e.g. multi-photon resonances

## Summary

- FELs produce polarized light with different polarization properties by utilizing variable polarization undulators
- Crossed polarized scheme has been **demonstrated** on a **seeded high gain FEL** in the VUV, with a degree of linear polarization  $>70\%$  (full aperture) and  $>90\%$  (pinhole)
- The **distributed scheme** provides an higher degree of polarization for the full beam
  - **Full polarization control**, in direction and type of polarization, is possible in all the presented schemes
- Linearly polarized radiation can be produced **without harmonic content**
