

The Push Towards Short X-Ray Pulse Generation Using Free Electron Lasers

A. Zholents

Outline

■ Where we are?

- State-of-the-art for a short x-ray pulse generation using FELs

■ Where we are going?

- Generation of attosecond x-ray pulses

- Short EUV/x-ray pulses are routinely produced at FLASH (10 – 70 fs), SCSS (~ 30 fs) , LCLS ($<10 - 80$ fs)
- All future x-ray FEL projects consider ultra-short x-ray pulse capabilities

Simple thoughts

- Short electron bunch radiates short x-ray pulse
- For a given peak current short bunch holds a low charge
- With low charge one may expect better 6D electron bunch brightness¹

$$B = \frac{2Q}{\gamma^3 \epsilon_x \epsilon_y \epsilon_z}$$

- Nearly FTL pulses from SASE¹

LCLS

$$Q = 1 \text{ nC}$$

$$B = 0.3 \text{ nC}/\mu\text{m}^3$$

$$\gamma \epsilon_{x,y} \approx 1 \mu\text{m}$$

$$\gamma \epsilon_z \approx \sigma_z(3 \text{ keV})/mc^2 = 6.5 \mu\text{m}$$

$$Q = 0.02 \text{ nC}$$

$$B = 4.5 \text{ nC}/\mu\text{m}^3$$

$$\gamma \epsilon_{x,y} \approx 0.15 \mu\text{m}$$

$$\gamma \epsilon_z \approx \sigma_z(1 \text{ keV})/mc^2 = 0.4 \mu\text{m}$$

Soft x-rays at 1.5 nm (simulations for LCLS)¹

1) Y. Ding, LBNL workshop, 08/2010

At undulator entrance, 4.3 GeV, Laser heater off

Under-compression: +1 deg off

Full-compression

Over-compression: -1 deg off

Actual measurements qualitatively confirm simulations.
Direct measurement of ultra-short x-ray pulse duration remains to be a difficult.

At 1.5 Å FEL performs well at full compression (slippage just right)

Measurement

Options for experiment utilizing synchronized pump and probe signals when electron bunch arrival time has a “large” jitter

- Use double slotted foil
- Split single x-ray pulse into two and adjust delay

- Create pump signal using coherent undulator radiation and adjust delay¹ (in case of an ultra-short e-bunch, ~ 1 fs)

1) considered by UCLA group

Precision synchronization of pump and probe pulses

- Seeded FELs naturally possess precise synchronization
 - if electron bunch length > laser pulse + jitter

- Current-enhanced SASE FEL --> same conclusion

Require synchronization of the seed and pump lasers ¹⁾

Attosecond pulse generation via electron interaction with a few cycle carrier-envelope phase stabilized laser pulse

Laser pulse ~ 5 fs

Small jitter in the electron bunch arrival time is not important – good for pump-probe experiments using variety of pump sources derived from initial laser signal

Basic idea:

Take an ultra-short slice of electrons from a longer electron bunch to produce a dominant x-ray radiation

Light interaction with relativistic electron

Laser pulse:
1 mJ, 5-fs
at 800 nm wave length
with CEP stabilization

Electron trajectory through undulator

Fragment of the electron bunch

Laser wavelength

$$\lambda_L = \lambda_u (1 + K^2/2) / 2\gamma^2$$

Undulator period

While propagating one undulator period, the electron is delayed with respect to the light on one optical wavelength

Energy modulation induced in the electron bunch during interaction with a ~ 1 mJ, 5 fs, 800 nm wave length laser pulse in a two period wiggler magnet with K value and period length matched to FEL resonance at 800 nm

Current enhancement method ^{*)}

800 – 1000 nm laser;

Summary: FELs – the light fantastic

- We are at the threshold of a new era of science, where for the first time, the new instruments, the x-ray FELs, are capable to study the matter with a single atom time and space resolution.
- FLASH, SCSS and LCLS routinely work with ultra-short XUV/x-ray pulses.
- Remarkably, adding attosecond capabilities to existing FELs require rather modest modifications.

Thank you for your attention
