Outline

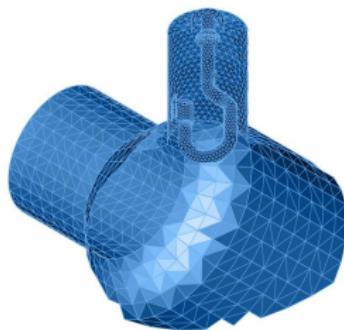

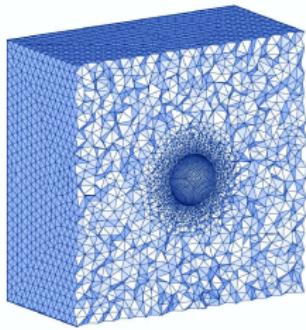

- Introduction
- Spatial Discretization by Discontinuous Galerkin FEM
- Numerical Integration
- Arbitrary high-order derivative time discretization
- Example: Lossless Rectangular Cavity
- Summary and Outlook

Introduction

Motivation

- Computation of electromagnetic field distribution as well as scattering parameters can be carried out in time domain
- Fast algorithms → implementation on parallel architectures (GPUs)
- Local time stepping (especially for grids with high aspect ratio)

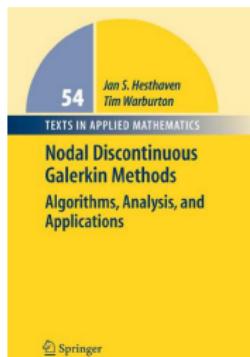

Introduction

Some information

- Implementation of the algorithms within the open source code NUDG++¹
- Uses Discontinuous Galerkin FEM (DG-FEM) for the spatial discretization of problems
- Well suited for parallel computing architectures (GPUs)
- We are focused on the **ADER-DG approach** (Arbitrary High-Order Derivative) as a special time integration scheme

¹ Nodal Unstructured Discontinuous Galerkin in C++ (some developers: N. Nunn, N. Gödel, C. R. Bahls, C. Potratz)

Introduction

Maxwell's Equations

- A more compact form of Faraday's and Ampère's law:

$$\frac{\partial \mathbf{u}}{\partial t} + \mathcal{A}_1 \frac{\partial \mathbf{u}}{\partial x} + \mathcal{A}_2 \frac{\partial \mathbf{u}}{\partial y} + \mathcal{A}_3 \frac{\partial \mathbf{u}}{\partial z} = 0, \quad (1)$$

where

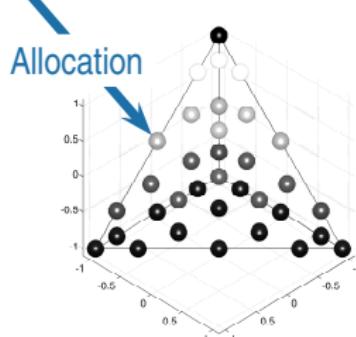

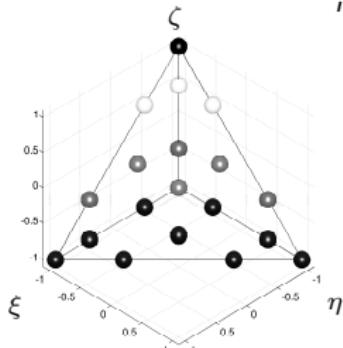

$$\mathbf{u}(x, y, z, t) = (H_x, H_y, H_z, E_x, E_y, E_z)^T \quad (2)$$

- To solve this ordinary differential equation, a physical initial condition and boundary conditions are still needed

Spatial Discretization by Discontinuous Galerkin FEM

- Computational domain $\Omega \in \mathbb{R}^3$ partitioned into tetrahedral elements D^k
- Approximate solution \mathbf{u}_h^k of (1) inside each tetrahedron D^k is given by:

$$\mathbf{u}_h^k = \sum_{i=1}^{N_p} \hat{\mathbf{u}}_i^k(t) \cdot \Phi_i^k(x, y, z) \quad (3)$$

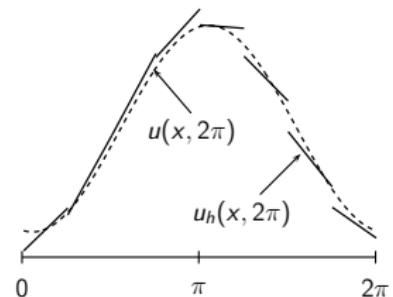

Reference element with the nodes on which the time-dependent degrees of freedom are defined. (left: 3rd order ansatz functions, right: 4th order ansatz functions)

Spatial Discretization by Discontinuous Galerkin FEM

- Multiplication of equation (1) by testfunction $\Phi_j(\mathbf{x})$, integration over D^k and finally integration by parts results in:

$$\int_{D^k} \Phi_j \frac{\partial u_h^k}{\partial t} dV + \boxed{\int_{\partial D^k} \Phi_j F_h^k dS} - \int_{D^k} \left(\frac{\partial \Phi_j}{\partial x} A_1 u_h^k + \dots \right) dV = 0 \quad (4)$$

- Coupling of adjacent elements by a numerical flux F_h^k
- Very suitable for the implementation on massively parallel architectures
- Integral formulation (4) results in a system of linear first order differential equations for every element separately

Example for central flux

Numerical Integration

- Application of explicit time integration schemes beneficial since equation (4) can be given in explicit manner for time derivatives without numerical effort
- Considered problem in compact form:

$$\frac{d\mathbf{u}}{dt} = \mathcal{L}(\mathbf{u}, t), \quad \mathbf{u}(t_0) = \mathbf{u}_0 \quad (5)$$

- Redraft of equation (5) in the integral form:

$$\mathbf{u}(t_{n+1}) = \mathbf{u}(t_n) + \int_{t_n}^{t_n + \Delta t} \mathcal{L}(\mathbf{u}, \tau) d\tau \quad (6)$$

- Key problem lies in the approximation of the integral in equation (6)

Arbitrary High-Order Derivative Time Discretization

Basic idea

- TAYLOR-expansion of the numerical solution in time, which allows for analytical time integration

ADER approach

- Taylor expansion in time

$$\boldsymbol{u}(x, y, z, t) = \sum_{p=0}^N \frac{t^p}{p!} \frac{\partial^p}{\partial t^p} \boldsymbol{u}(x, y, z, t) \Big|_{t=t_0} \quad (7)$$

- Replace time derivates by spatial derivates based on problem (1)

$$\frac{\partial^p \boldsymbol{u}}{\partial t^p} = (-1)^p \left(\mathcal{A}_1 \frac{\partial}{\partial x} + \mathcal{A}_2 \frac{\partial}{\partial y} + \mathcal{A}_3 \frac{\partial}{\partial z} \right)^p \boldsymbol{u} \quad (8)$$

Arbitrary high-order derivative time discretization

Implementation - Replace time derivates

- Putting all together with the DG approximation (3):

$$\mathbf{u}_h^k(\xi, \eta, \zeta, t) = \sum_{p=0}^N \frac{t^p}{p!} (-1)^p \left(\mathcal{A}_1^* \frac{\partial}{\partial \xi} + \dots \right)^p \hat{\mathbf{u}}_i^k(t_0) \Phi_i(\xi, \eta, \zeta) \quad (9)$$

- Projection onto each basis function yields the time evolution of the degrees of freedom $\hat{\mathbf{u}}_j^k$ within the time step Δt :

$$\hat{\mathbf{u}}_j^k(t) \langle \Phi_n | \Phi_j \rangle = \langle \Phi_n | \sum_{p=0}^N \frac{t^p}{p!} (-1)^p \left(\mathcal{A}_1^* \frac{\partial}{\partial \xi} + \dots \right)^p | \Phi_i \rangle \hat{\mathbf{u}}_i^k(t_0) \quad (10)$$

Mass matrix $\mathcal{M}_{(n,j)}$

structure like $\langle \Phi_n | \frac{\partial^p}{\partial \xi^\lambda \partial \eta^\mu \partial \zeta^\nu} \Phi_i \rangle$

Arbitrary high-order derivative time discretization

Implementation - Time integration

$$\int_{t_0}^{t_0 + \Delta t} \hat{u}_j^k(t) dt = \underbrace{\mathcal{M}_{(n,j)}^{-1} \langle \Phi_n | \sum_{p=0}^N \frac{\Delta t^{(p+1)}}{(p+1)!} (-1)^p \left(\mathcal{A}_1^* \frac{\partial}{\partial \xi} + \dots \right)^p | \Phi_i \rangle \hat{u}_i^k(t_0)}_{\text{time integration operator}} \quad (11)$$

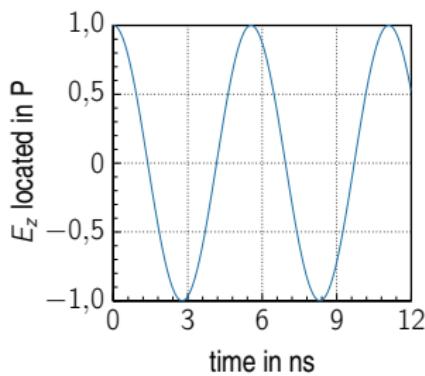

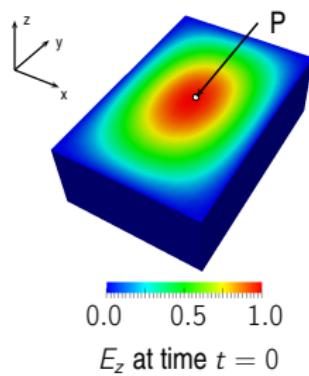

$$\mathbf{u}(t_{n+1}) = \mathbf{u}(t_n) + \int_{t_n}^{t_n + \Delta t} \mathcal{L}(\mathbf{u}, \tau) d\tau \quad (12)$$

Example: Lossless Rectangular Cavity

Simulation model

- Helmholtz equation for this geometry can be solved analytically
- Size: $1.0 \text{ m} \times 1.5 \text{ m} \times 0.5 \text{ m}$, material: ϵ_0, μ_0
- Fundamental mode:

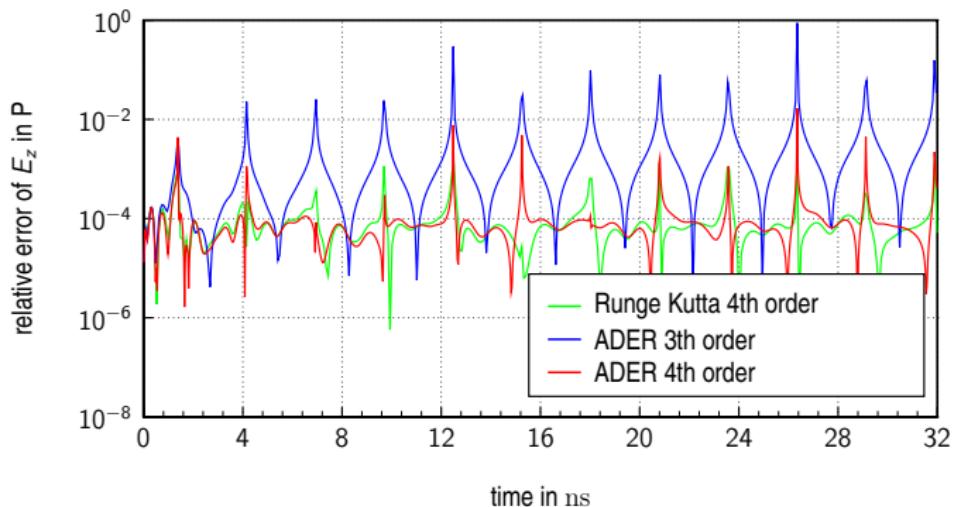

Example: Lossless Rectangular Cavity

Results with 3rd order ansatz functions

- Comparison between ADER time integration scheme 3rd and 4th order and a 4th order Runge-Kutta scheme

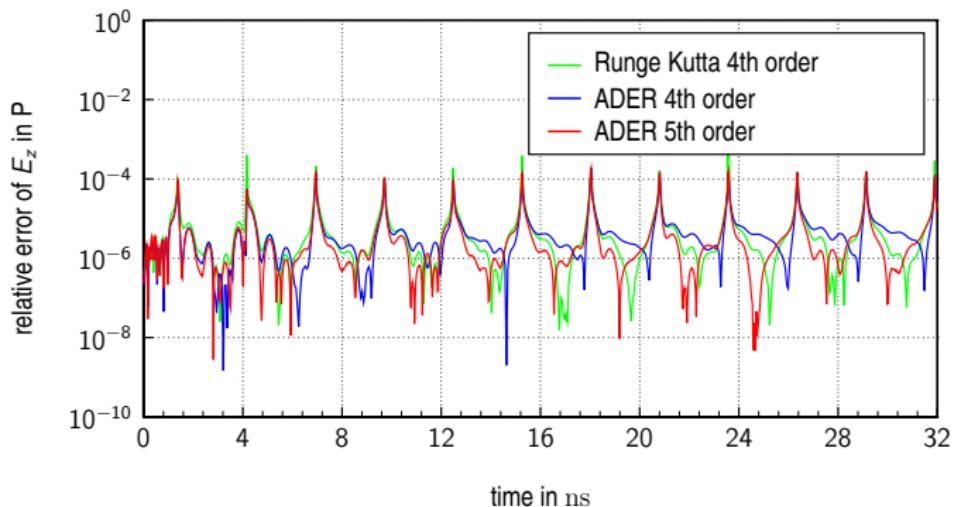

Example: Lossless Rectangular Cavity

Results with 4th order ansatz functions

- Comparison between ADER time integration scheme 3rd and 4th order and a 4th order Runge-Kutta scheme

Summary and Outlook

- By using only one CPU core the 4th order Runge Kutta is ~ 3 times faster than the ADER aproach in the same order
- 3rd order Adams-Bashforth is ~ 1.7 times faster but with a lower convergence order
- For higher order basis functions these ratios reduce → especially suitable for high accuracy
- Implementation on parallel architectures probably improves also these ratios related to the ADER aproach
- Time integration for the ADER scheme is relativly expensive in storage and computation but stable for a larger time step
- Next Step: Implementation for GPUs (via Cuda or OpenCL)
