

Undulator Radiation Inside a Dielectric Waveguide

A.S. Kotanjyan

Department of Physics, Yerevan State University Yerevan, Armenia

Content

- Motivation
- On features of the radiation from an electron moving along a helix around a cylindrical waveguide
- + Electromagnetic fields Inside a cylinder
- + Radiation fields inside a dielectric cylinder
- + Conclusion

Motivation

The motion of charged particles along a helical orbit is used in helical undulators for generating electromagnetic radiation

+ The Unique Characteristics of undulator radiation are the following:

- Broad Spectrum (from radio or millimeter waves to hard X-rays
- High Flux
- High Brilliance: highly collimated photon beam generated by a small divergence and small size source (spatial coherence)
- High Stability: submicron source stability
- Polarization: both linear and circular
- Pulsed Time Structure: pulsed length down to tens of picoseconds allows the resolution of process on the same time scale

Experimental Techniques and Usage

 Synchrotron light is an ideal tool for many types of research and also has industrial applications

Some of the experimental techniques in synchrotron beamlines are:

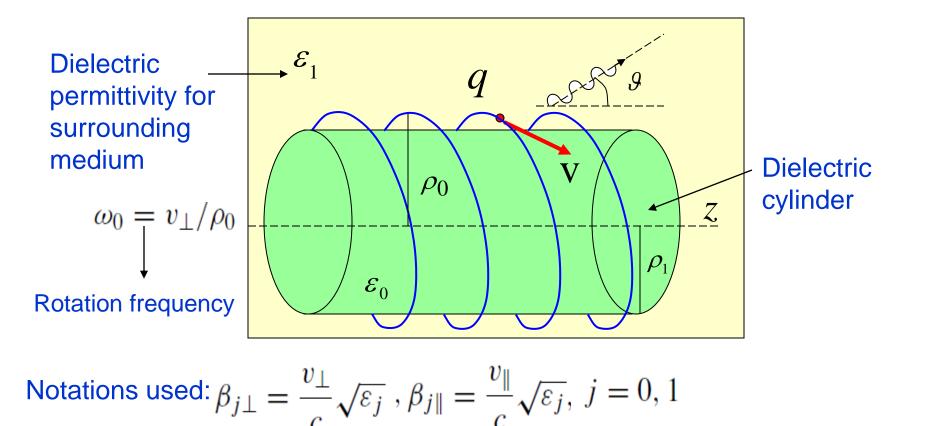

- * <u>Structural analysis</u> of <u>crystalline</u> and <u>amorphous</u> materials
- Powder diffraction analysis
- X-ray crystallography of proteins and other macromolecules
- Tomography
- Photolithography for <u>MEMS</u> structures as part of the <u>LIGA</u> process.
- Photoemission spectroscopy and Angle resolved photoemission spectroscopy
- High energy X-rays which can penetrate matter and interact with atoms
- High concentration, tunability and polarization thus ensuring focusing accuracy for even the smallest of targets

Radiation processes in medium

- Wide applications of synchrotron radiation motivate the importance of investigations for various mechanisms of controlling the radiation parameters
- From this point of view, it is of interest to consider the influence of a medium on the spectral and angular distributions of the radiation
- It is well known that the presence of medium gives rise to new types of radiation processes:
 - Cherenkov radiation
 - Transition radiation
 - Diffraction radiation
- High energy electromagnetic processes essentially change their characteristics when boundaries are present

We consider combined effects of medium and boundaries

Geometry of the problem

The components of the charge velocity along the axis of the cylinder (drift velocity) and on the perpendicular plane we will denote by v_{\parallel} and v_{\perp} respectively

Point charge q moving along the helical trajectory of radius $\rho_0 > \rho_1$ around a dielectric cylinder

Radiation intensity in the exterior medium

+ Under the Cherenkov condition, $\beta_{1\parallel} > 1$, the total radiation intensity at large distances from the charge trajectory is presented in the form

$$I = I_0 + I_{m \neq 0}$$

 $+ I_0$ describes the radiation with a continuous spectrum propagating along the Cherenkov cone of the external medium $\vartheta = \vartheta_0 \equiv \arccos\left(\beta_{1\parallel}^{-1}\right)$

+
$$I_{m\neq0} = \sum_{m=1}^{\infty} \int d\Omega \frac{dI_m}{d\Omega}$$
, $d\Omega = \sin \vartheta \, d\vartheta \, d\phi$,
 $\omega_m = \frac{m\omega_0}{|1 - \beta_{1\parallel}\cos \vartheta|}$, $m = 1, 2, ..., \omega_0 = v_{\perp}/\rho_0$

• Normal Doppler effect $\beta_{1\parallel} < 1$ and $\beta_{1\parallel} > 1, \vartheta > \vartheta_0$,

 v_{\perp}/ρ_0

• Anomalous Doppler effect $\vartheta < \vartheta_0$, in the case $\beta_{1\parallel} > 1$

Features of the radiation The asymptotical cases

Induced by the presence of the cylinder

Contribution of the harmonics with m > 1 is small compared to that in the fundamental one, m = 1

In the limit ρ₁ → 0, when the radius of cylinder is small, the difference between the radiation intensities in the cases when the cylinder is present and absent, $dI_m/d\Omega - dI_m^{(0)}/d\Omega \propto \rho_1^{2m}$ for $m \ge 1$ $\frac{dI_m^{(0)}}{d\Omega} = \frac{q^2 \omega_0^2 m^2}{2\pi c \sqrt{\varepsilon_1} |1 - \beta_{1\parallel} \cos \vartheta|^3} \left[\beta_{1\perp}^2 J_m'^2(\lambda_1 \rho_0) + \left(\frac{\cos \vartheta - \beta_{1\parallel}}{\sin \vartheta} \right)^2 J_m^2(\lambda_1 \rho_0) \right]$

In the same limit and for the radiation corresponding to m = 0, the part induced by the cylinder vanishes like ρ_1^2

Features of the radiation

★ Behavior of the radiation intensity near the Cherenkov angle when $\frac{\mathrm{d}I_m}{\mathrm{d}\Omega} \propto |1 - \beta_{1\parallel} \cos \vartheta|^{-2}, \quad |1 - \beta_{1\parallel} \cos \vartheta| \ll 1$

- + Near the Cherenkov cone the frequencies of the radiated photons are large and the dispersion of the dielectric permittivity ε_1 should be taken into account
- + For the radiation intensity in a homogeneous medium with dielectric permittivity ε_1 we have the same behavior
- + For the charge helical motion inside the dielectric cylinder ($\rho_0 < \rho_1$) the behavior of the radiation intensity near the Cherenkov cone is radically different for

$$\beta_{0\parallel} > 1 \qquad \frac{\mathrm{d}I_m}{\mathrm{d}\Omega} \propto |1 - \beta_{1\parallel} \cos \vartheta|^{-4}$$

$$\beta_{0\parallel} < 1 \qquad \frac{\mathrm{d}I_m}{\mathrm{d}\Omega} \propto |1 - \beta_{1\parallel} \cos \vartheta|^{-4} \exp\left[-2(\omega_m/v_{\parallel})(\rho_1 - \rho_0)\sqrt{1 - \beta_{0\parallel}^2}\right]$$

Strong peaks in the radiation intensity

Strong narrow peaks are present in the angular distribution for the radiation intensity at a given harmonic m

+ The condition for the appearance of the peaks is obtained from the equation determining the eigenmodes for the dielectric cylinder by the replacement $H_m \rightarrow Y_m$

Hankel function
of the first kind
$$\sum_{l=\pm 1} \left[\frac{\lambda_1}{\lambda_0} \frac{J_{m+l}(\lambda_0 \rho_1) Y_m(\lambda_1 \rho_1)}{J_m(\lambda_0 \rho_1) Y_{m+l}(\lambda_1 \rho_1)} - 1 \right]^{-1} = \frac{2\varepsilon_0}{\varepsilon_1 - \varepsilon_0}$$
$$\lambda_j^2 = \frac{\omega_m^2(k_z)}{c^2} \varepsilon_j - k_z^2, \qquad j = 0, 1, \quad \omega_m(k_z) = m\omega_0 + k_z v_{\parallel}$$

This equation has no solutions for the case $\epsilon_0 < \epsilon_1$

Strong peaks in the radiation intensity

As necessary conditions for the presence of the strong narrow peaks in the angular distribution for the radiation intensity one has

$$\frac{\omega_0 \rho_0}{c} \sqrt{\varepsilon_1} \sin \vartheta < |1 - \beta_{1\parallel} \cos \vartheta| < \frac{\omega_0 \rho_1}{c} \sqrt{\varepsilon_0 - \varepsilon_1 \cos^2 \vartheta}$$

These conditions can be satisfied only if we have

$$\varepsilon_0 > \varepsilon_1, \qquad \tilde{v}\sqrt{\varepsilon_0}/c > 1, \text{ where } \tilde{v} = \sqrt{v_{\parallel}^2 + \omega_0^2 \rho_1^2}$$

velocity of the charge image

Analytic estimates for the heights and widths of peaks on the cylinder surface

Angular dependence of the radiation intensity near the peak

$$\frac{\mathrm{d}I_m}{\mathrm{d}\Omega} \propto \frac{1}{(\vartheta - \vartheta_p)^2 / b_p^2 + 1} \left(\frac{\mathrm{d}I_m}{\mathrm{d}\Omega}\right)_{\vartheta = \vartheta_p}, \quad b_p \propto \exp[-2m\zeta(\lambda_1\rho_1/m)]$$

+ Angular widths of the peaks: $\Delta \vartheta \propto \exp[-2m\zeta(\lambda_1\rho_1/m)]$

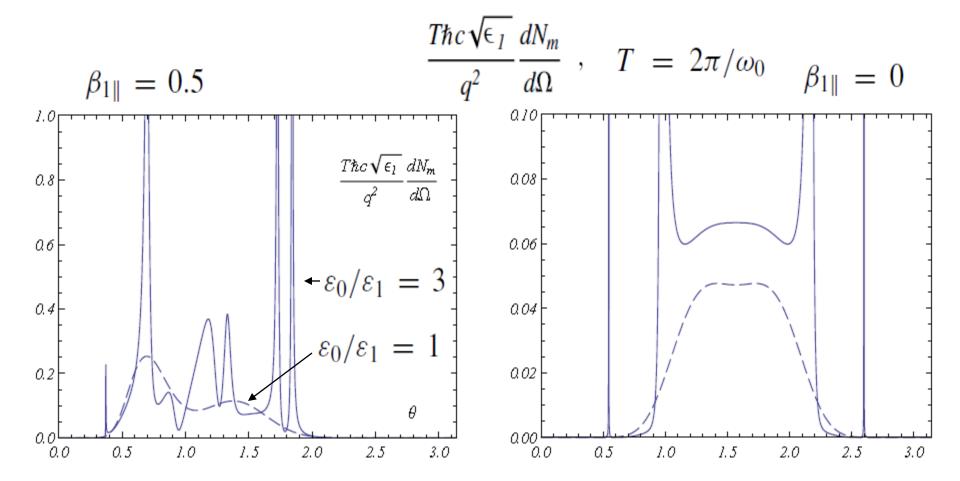

$$\zeta(z) = \ln \frac{1 + \sqrt{1 - z^2}}{z} - \sqrt{1 - z^2}, \quad \lambda_1 = \frac{m\omega_0}{c} \frac{\sqrt{\varepsilon_1} \sin \vartheta}{1 - \beta_{1\parallel} \cos \vartheta}$$

Numerical examples

Angular density for the Number of the Radiated Quanta

$$\frac{\mathrm{d}N_m}{\mathrm{d}\Omega} = \frac{1}{\hbar\omega_m} \frac{\mathrm{d}I_m}{\mathrm{d}\Omega}$$

$$\beta_{1\perp} = 0.9, \, \rho_1 / \rho_0 = 0.95, \, m = 10$$

Radiation Inside a Dielectric Waveguide

Vector potential is presented as the Fourier expansion

$$A_l(\mathbf{r},t) = \sum_{m=-\infty}^{\infty} e^{im(\phi-\omega_0 t)} \int_{-\infty}^{\infty} dk_z e^{ik_z(z-v_{\parallel}t)} A_{ml}(m,k_z,\rho)$$

Fourier coefficients for the fields determined have poles corresponding to the zeros of the function

$$\begin{split} \alpha_m &= \frac{\varepsilon_0}{\varepsilon_1 - \varepsilon_0} - \frac{\lambda_0 J_m(\lambda_0 \rho_1)}{2} \sum_{l=\pm 1} l \frac{H_{m+l}(\lambda_1 \rho_1)}{V_{m+l}^H} \\ \text{Notation:} \quad V_m^F &= J_m(\lambda_0 \rho_1) \frac{\partial F_m(\lambda_1 \rho_1)}{\partial \rho_1} - F_m(\lambda_1 \rho_1) \frac{\partial J_m(\lambda_0 \rho_1)}{\partial \rho_1}, \ F = J, H \\ \lambda_j^2 &= \frac{\omega_m^2(k_z)}{c^2} \varepsilon_j - k_z^2, \qquad j = 0, 1, \end{split}$$

+ Function α_m has zeros only under the conditions $\lambda_1^2 < 0 < \lambda_0^2 \Rightarrow \varepsilon_1 < \varepsilon_0$

- Corresponding modes in the exterior region are exponentially damped with the distance from the cylinder surface
- These modes are the eigenmodes of the dielectric cylinder and they correspond to the waves propagating inside the cylinder

Poles and the integration contour

+ We denote by $\lambda_0 \rho_1 = \lambda_{m,s}, s = 1, 2, ...,$ the solutions to equation $\alpha_m = 0$

Corresponding modes for
$$k_z = k_{m,s}^{(\pm)}$$
 $\sigma = +(-)$ for $z - v_{\parallel}t > 0$ $(z - v_{\parallel}t < 0)$

$$k_{m,s}^{(\pm)} = \frac{m\omega_0\sqrt{\varepsilon_0}}{c(1 - \beta_{0\parallel}^2)} \left[\beta_{0\parallel} \pm \sqrt{1 + b_{m,s}^2(\beta_{0\parallel}^2 - 1)}\right], \quad b_{m,s} = \frac{c\lambda_{m,s}}{m\omega_0\rho_1\sqrt{\varepsilon_0}}$$

★ For β_{0||} < 1, the condition for k^(±)_{m,s} to be real defines the maximum value for s: $\lambda_{m,s_m} < \frac{m\omega_0 \rho_1 \sqrt{\varepsilon_0}}{c\sqrt{1-\beta_{0||}^2}} < \lambda_{m,s_m+1}$

- If the Cherenkov condition β_{0∥} > 1 is satisfied, the upper limit s is determined by the dispersion law for the dielectric permittivity via the condition ε₀(ω_m) > c²/v_∥²
- + Integration contour in the complex plane k_z should be specified: By taking into account the imaginary part of the dielectric permittivity it can be seen:
 - For $\beta_{0\parallel} < 1$ in the integral over k_z the contour avoids the poles $k_{m,s}^{(-)}$ from above and the poles $k_{m,s}^{(+)}$ from below
 - For $\beta_{0\parallel} > 1$ poles $k_{m,s}^{(\pm)}$ should be avoided from above

Electromagnetic fields inside the cylinder

+ Closing the integration contour by the large semicircle, under the condition $\beta_{0\parallel} < 1$ one finds

 $F_{l}^{(\text{rad})}(\mathbf{r},t) = \sigma F_{l}^{(\sigma)}(\mathbf{r},t) = \sigma 4\pi \operatorname{Re}\left[i\sum_{m=1}^{\infty} e^{im(\phi-\omega_{0}t)} \sum_{s=1}^{s_{m}} \operatorname{Res}_{k_{z}=k_{m,s}^{(\sigma)}} e^{ik_{z}(z-v_{\parallel}t)} F_{ml}(k_{z},\rho)\right]$ $\sigma = +(-) \text{ for } z - v_{\parallel}t > 0 (z - v_{\parallel}t < 0)^{\left[1 + \frac{1}{2}\right]} e^{im(\phi-\omega_{0}t)} \sum_{s=1}^{s_{m}} \operatorname{Res}_{k_{z}=k_{m,s}^{(\sigma)}} e^{ik_{z}(z-v_{\parallel}t)} F_{ml}(k_{z},\rho)$

- Describes waves propagating
 - Along the positive direction of the axis z for $\sigma = +$ and for $\sigma = -, b_{m,s} < 1$

 $b_{m,s} = \frac{c\lambda_{m,s}}{m\omega_0\rho_1\sqrt{\varepsilon_0}}$

• Along the negative direction to the axis z for $\sigma = -, 1 < b_{m,s} < 1/\sqrt{1-\beta_{0\parallel}^2}$

← Radiation fields under the condition $\beta_{0\parallel} > 1$ Heaviside unit $F_l^{(\text{rad})}(\mathbf{r}, t) = -\sum_{\sigma=\pm} F_l^{(\sigma)}(\mathbf{r}, t)\theta(v_{\parallel}t - z)$ step function

Describes waves propagating

- Along the positive direction of the axis *z* for $\sigma = +$ and for $\sigma = -, b_{m,s} > 1$
- Along the negative direction to the axis *z* for $\sigma = -, b_{m,s} < 1$

+ For $b_{m,s} > 1$ there are no waves propagating along the negative direction of the axis z

All these features are for the laboratory system

Radiation energy flux inside the cylinder

+ Energy flux through the cross section of the cylinder

$$I = \frac{c}{4\pi} \int_0^{\rho_1} d\rho \int_0^{2\pi} d\phi \,\rho(E_\rho H_\phi - E_\phi H_\rho)$$

+ For simplicity consider the case $v_{\parallel} = 0$

$$I = \frac{q^2 v^2}{8\varepsilon_0} (\varepsilon_1 - \varepsilon_0)^2 \sum_{m=1}^{\infty} \sum_{s=1}^{s_m} \frac{J_m^{-2}(\lambda_{m,s})}{K_m^2(\lambda_{m,s}^{(1)})} \frac{\lambda_{m,s}^2}{U_m'^2(k_{m,s})} \frac{k_{m,s}}{m\omega_0} \left(\sum_{l=\pm 1} \frac{lK_{m+l}(\lambda_{m,s}^{(1)}\rho_{01})}{V_m - lmu} \right)^2 \\ \times \sum_{p=\pm 1} \left[\left(\frac{m^2 \omega_0^2}{c^2} \rho_1^2 \varepsilon_0 + k_{m,s}^2 \rho_1^2 \right) (V_m + pmu)^2 - \lambda_{m,s}^2 \left(V_m^2 - m^2 u^2 \right) \right] \\ \times \left[J_{m+p}'^2(\lambda_{m,s}) + J_{m+p}^2(\lambda_{m,s}) \left(1 - \frac{(m+p)^2}{\lambda_{m,s}^2} \right) \right].$$

Notations

$$\lambda_{m,s} = \rho_1 \sqrt{\left(\frac{m\omega_0}{c}\right)^2 \varepsilon_0 - k_{m,s}^2}, \quad \lambda_{m,s}^{(1)} = \rho_1 \sqrt{k_{m,s}^2 - \left(\frac{m\omega_0}{c}\right)^2 \varepsilon_1}$$
$$V_m = \lambda_{m,s}^{(1)} \frac{J'_m(\lambda_{m,s})}{J_m(\lambda_{m,s})} + \lambda_{m,s} \frac{K'_m(\lambda_{m,s}^{(1)})}{K_m(\lambda_{m,s}^{(1)})}, \quad u = \frac{\lambda_{m,s}}{\lambda_{m,s}^{(1)}} + \frac{\lambda_{m,s}^{(1)}}{\lambda_{m,s}},$$

Radiation energy flux inside the cylinder (continued)

+ Notations

$$U_{m} = V_{m} \left(\varepsilon_{0} \lambda_{m,s}^{(1)} \frac{J_{m}'(\lambda_{m,s})}{J_{m}(\lambda_{m,s})} + \varepsilon_{1} \lambda_{m,s} \frac{K_{m}'(\lambda_{m,s}^{(1)})}{K_{m}(\lambda_{m,s}^{(1)})} \right) - m^{2} \frac{\lambda_{m,s}^{2} + \lambda_{m,s}^{(1)2}}{\lambda_{m,s}^{2} \lambda_{m,s}^{(1)2}} \left(\varepsilon_{1} \lambda_{m,s}^{2} + \varepsilon_{0}^{2} \lambda_{m,s}^{(1)2} \right)$$

+ Eigenmodes of the cylinder are solutions of the equation

$$U_m = 0$$

+ Number of the radiated quanta at a given harmonic *m* per period of the charge rotation $TI_{m} = 2\pi$

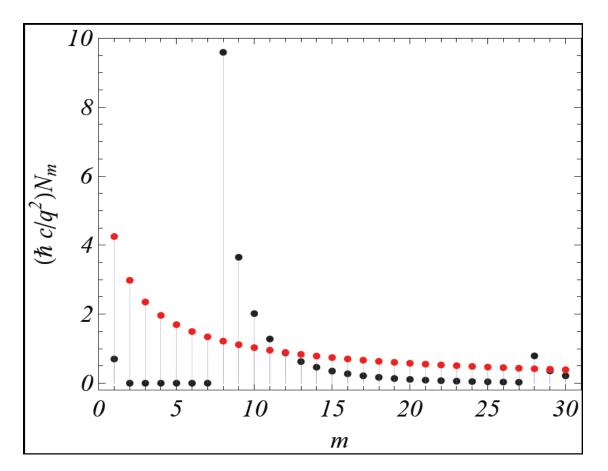

$$N_m = 2 \frac{1}{\hbar m \omega_0} \,, \ T = \frac{2\pi}{\omega_0}$$

Corresponds to that we have the same amount of the energy flux in the regions z > 0 and z < 0

In addition to the radiation propagating inside the dielectric cylinder, in the exterior region we have also radiation fields localized near the surface of the cylinder

+ These fields are the tails of the eigenmodes for the dielectric cylinder

 ★ Values of the parameters: Electron energy=2MeV, $\varepsilon_1 = 1$, $\varepsilon_0 = 3$, $\rho_1 / \rho_0 = 0.95$ Red points -> Synchrotron radiation in the absence of the cylinder

At m=8 and m=28 new modes of the dielectric cylinder appear

Conclusions

- We have investigated the properties of the radiation from a charged particle moving along a helical orbit around a dielectric cylinder
- Under certain conditions on the parameters strong narrow peaks appear in the angular distribution of the radiation intensity in the exterior medium
- We have specified the conditions for the appearance of the peaks and analytically estimated their heights and widths
- Peaks are present only when dielectric permittivity of the cylinder is greater than the permittivity for the surrounding medium and the Cherenkov condition is satisfied for the velocity of the charge image on the cylinder surface and the dielectric permittivity of the cylinder
- Presence of the cylinder provides a possibility for an essential enhancement of the radiated power as compared to the radiation in a homogeneous medium

Conclusions (continued)

- Radiated energy inside the cylinder is redistributed among the cylinder modes and, as a result, the corresponding spectrum differs significantly from the homogeneous medium or free-space results
- Radiation emitted on the waveguide modes propagates inside the cylinder and the waveguide serves as a natural collector for the radiation
- This eliminates the necessity for focusing to achieve a high-power spectral intensity
