Abstract

Synchrotron radiation source to generate a coherent light by using a laser seeding technique are under development at the UVSOR-II. In the past experiments, we have succeeded in generating coherent harmonics (CHs) in deep ultraviolet (DUV) and vacuum ultraviolet (VUV) region and also in generating CHs with variable polarizations in DUV region.

This time we have successfully observed CHs up to the 9th harmonic over a wide peak power range regime, for the first time. In addition, we observed CH intensity oscillations after the first maximum. In this paper, we discuss the results of some systematic measurements and those analytical and particle tracking simulations.

INTRODUCTION

The laser seeding technique, injecting laser with full coherence to electron bunch into undulator, is used for single-pass seeded free-electron laser (FEL) [1] to improve temporal self-amplified coherence of spontaneous emission (SASE)-FEL, for coherent harmonic generation (CHG) [2-4], and for high-gain harmonic generation (HGHG) [5].

At UVSOR-II, a 750 MeV synchrotron light source, a resonator-type FEL has been studied for many years [6-8]. These years, by utilizing a part of the FEL system, studies on coherent synchrotron radiation (CSR) in terahertz range and CHG in DUV range have been performed by using a femto-second laser system. In the past studies, DUV CHs with circular polarization have been successfully generated [9-10]. In addition, the CHG in VUV region has successfully been measured up to 9th harmonic.

EXPERIMENTAL SETUP

Configuration

Figure 1 illustrates the experimental setup. Femtosecond Ti: Sapphire laser system for injection laser consist of a mode-locked oscillator (Mira, COHERENT), which is synchronized with the RF acceleration of the storage ring, and a regenerative amplifier (Legend, COHERENT). The laser pulse is injected with 1 kHz repetition rate via a sapphire window. A wave plate and polarizer for changing laser power, a lens pair for beam expander, and a focusing lens (5000 mm of focal length) are settled upstream of the sapphire window and the laser

* current address is PhLAM, Universite Lille 1, France * curi # taka 3098 # takanori.tanikawa@phlam.univ-lille1.fr

pulse is focused into the modulator part of optical klystron (OK). The CHs generated by the interaction between the laser pulse and the electron beam are introduced to a light diagnostics section or to a VUV spectrometer.

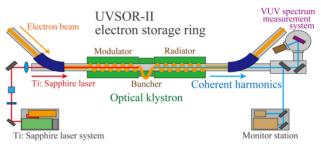

Figure 1: Schematic drawing of experimental setup in coherent harmonic generation experiment.

Parameters

Table 1 shows parameters of the electron beam, the OK, and Ti: Sapphire laser in this experiment.

Table 1: Experimental Parameters

| Table 1: Experimental Parameters | |
|----------------------------------|---------------------------|
| < Electron beam > | |
| Beam energy | 600 MeV |
| Beam current | 30 mA |
| Bunch length | 121 ps |
| Natural energy spread | 3.4 * 10-4 |
| Revolution frequency | 5.64 MHz |
| <optical klystron=""></optical> | |
| Period length | 110 mm |
| Number of periods | 9 + 9 |
| K value | 6.18 |
| N_d | 45 |
| <ti: laser="" sapphire=""></ti:> | |
| Wavelength | 800 nm |
| Pulse energy | ~2.5 mJ |
| Pulse duration | $130 \sim 1.3 \text{ ps}$ |
| Repetition rate | 1 kHz |

Methods

Spacial and temporal alignments between the electron beam and Ti: Sapphire laser are monitored at the light diagnostic section. The spacial alignment is performed that the electron beam and injected laser are overlapped in whole modulator part of the OK by using CCD camera. The rough temporal alignment is performed by using pinphoto diode and the precise temporal alignment is performed by using streak camera (C5680, Hamamatsu Photonics). The spectrum measurements of CHs in VUV region are performed by using VUV spectrum measurement system. The system are constructed by an aluminium coated pre-focusing mirror, a spectrometer (VMK-200-UHV, Vacuum & Optical Instruments) with a platinum coated concave replica grating of 2400 grooves/mm, and an electron multiplier tube (R5150MOD, Hamamatsu Photonics) as a detector.

EXPERIMENTAL RESULT

As the results of spectrum measurements, VUV CHG has been observed up to 9th harmonic.

Saturation Effect on VUV Coherent Harmonic Generation

Figure 2 and 3 show the dependences of CHs intensities on the peak power of injected laser. As shown in Figs. 2 and 3, an intensity saturation of CHs has been observed. In Fig. 2, intensities of 5^{th} , 7^{th} , and 9^{th} CHs are plotted as functions of peak laser power with laser pulse duration of 870 fs. Dots represent measured values, and solid curves represent analytical simulation results [for the analytical equations, see eq. $(1) \sim (4)$]. As the peak laser power increases, CHs intensities also increase but tend to saturate and shows a peak around 1 GW. In Fig. 3 also, intensity saturation has been observed with laser pulse duration of 190 fs.

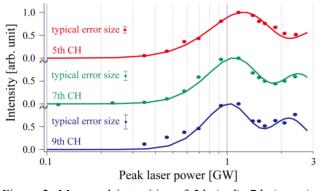

Figure 2: Measured intensities of 5th (red), 7th (green), and 9th (blue) CHs plotted as functions of the peak power of injected laser, for laser pulse duration of 870 fs. Dots represent measured values, and solid curves represent analytical simulation results.

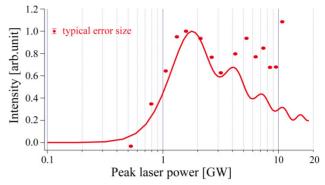

Figure 3: Measured intensity of 5th CH plotted as a function of the peak power of injected laser, for laser pulse duration of 190 fs. Dots represent measured values, and solid curve represents the analytical simulation result.

In order to compare between experimental results and analytical ones, we use the following formula which give the intensity of the *i*-th harmonic [11],

$$I_{\rm CH}^{(i)} = N_{\rm e}^2 F^{(i)} I_{\rm SE,1}^{(i)},$$
 (1)

where $N_{\rm e}$ is the number of the electrons in the bunch, $F^{(i)}$ is the form factor given by the square of the Fourier transform of the normalized longitudinal electron density distribution, and $I_{\rm SE,1}$ is the intensity of the SE from a single electron. Variables in the eq. (1) are given by the following formula,

$$F^{(i)} = [2]_i(i\eta)]^2, \tag{2}$$

$$\eta = 4\pi N_{\rm d} \frac{\Delta E_{\rm modulation}}{E},\tag{3}$$

and

$$\Delta E_{\text{modulation}} = -\frac{e^2 \lambda_{\text{u}}^{BL}}{4 \pi m_0 c} E_{\text{L}}.$$
 (4)

Here, J_i is an *i*-th order Bessel function, $\Delta E_{\text{modulation}}$ is the amplitude of energy modulation, E is the electron energy. e is the electron charge, λ_u , B and L are the period length of magnet, the peak magnetic field, and the length of the OK modulator, respectively, m_0 is the electron rest mass, c is the speed of light, and E_L is the amplitude of the laser electric field. In the eq. (1), the effects of the emittance and energy spread of the electron beam are ignored. About solid curves in Figs. 2 and 3, it assumes the longitudinal distribution of the laser power is Gaussian. The energy modulation was calculated as a function of the position in the electron bunch approximately. As shown in Fig. 2, our calculations reproduced the observed variation in the width and the position of the intensity peak for the three harmonics. The peak position shifts to lower peak laser powers with increasing order of the CH. Figure 3 shows that our calculation also reproduced several other peaks observed in the deep saturation

regime qualitatively. A more precise simulation, which would include three-dimensional effects, is required to achieve quantitative agreement.

To understand these results deeply, Fig. 4 shows an example of results of a one-dimensional particle tracking simulation of the bunching process in the saturated

The sinusoidal energy modulation produced by the laserelectron interaction is converted to a density modulation, and the bunching is optimized at a certain peak laser power. Considering for the results of Fig. 2, the Fourier component is largest near the optimal bunching condition, where the bunching is sharpest, in the case of high-order CHs. However, for lower-order CHs, the Fourier component is largest when the electrons are slightly overbunched because of contribution of more electrons. For this reason, the lower-order CHs reach their maximum intensity at larger peak laser powers. Overbunching causes a smearing of the electron distribution but leads to further bunching subsequently at a peak laser power about 20 times greater than for the optimal condition. This regime is inaccessible to our experimental setup. However, the experiments and simulations in Fig. 3 show several peaks appearing beyond the first maximum, which can be explained by an additive interference of the double-peak structure shown in Fig. 4. When the separation of the peaks equals a multiple of the harmonic wavelength, interference produces peaks in the Fourier components, and hence in the CH intensities. The second peak in Fig. 3, which corresponds to Fig. 4, can be explained in the same manner [12].

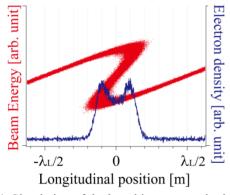

Figure 4: Simulation of the bunching process in the OK at the formation of the second peak in Fig. 3. The blue curve (longitudinal electron density distribution) effectively represents a histogram of the data in red.

GENERATION OF SHORTER WAVELENGTH COHERENT **HARMONICS**

For a generation of shorter wavelength CHs at UVSOR-II and an establishment the laser seeding technology for the single-pass FEL, the seed light source by using nonlinear crystal and based on higher harmonic generation (HHG) in a gas are under development in UVSOR-II. Now the HHG system has been constructed. The target wavelength is 160 nm (5th harmonic of Ti: Sapphire laser). The HHG experiment is under studying and HHG-seeded CHG experiment will be demonstrated in the future.

SUMMARY AND FUTURE PLAN

We have successfully observed CHs up to the 9th harmonic over a wide peak power range. In addition, we observed CH intensity oscillations after the first maximum. We compared these measurements with a onedimensional calculation that qualitatively reproduced our experimental results, and showed that the intensity oscillation originates from the formation of the doublepeak structure in the longitudinal density distribution of the electron beam. Further simulation would consider the three-dimensional distributions of the laser and the electron beams. This research is useful to the nextgeneration seeded FELs. Finally, HHG system for the seed light is under development for shorter wavelength CHG.
