FRONT-END LINAC DESIGN AND BEAM DYNAMICS SIMULATIONS FOR MYRRHA *

Institut für Angewandte Physik, Goethe-Universität, D-60438 Frankfurt a. M., Germany

Abstract
A 17MeV, 176MHz, and CW (Continuous Wave) proton linac is being developed as the front end of the driver accelerator for the MYRRHA facility in Mol, Belgium. Based on the promising preliminary design, further simulation and optimization studies have been performed with respect to code benchmarking, RFQ simulation using realistic LEBT output distributions, and an updated CH-DTL design with more detailed inter-tank configurations. This paper summarizes the new results.

PRELIMINARY DESIGN
Following the EUROTRANS project [1], MAX [2] (MYRRHA Accelerator eXperiment research and development programme) is the ongoing European ADS (Accelerator-Driven System) project. For the front end of the driver linac, the EUROTRANS-style injector [3] that consists of one RFQ (Radio-Frequency Quadrupole), two RT (room-temperature) and four SC (superconducting) CH (Cross-bar H-mode)-DTL (Drift-Tube Linac) cavities will be still adopted, but with many new concepts [4].

The most important idea is to halve the RF frequency from 352MHz to 176MHz, which improves the RFQ shunt impedance significantly (see Fig. 1), enlarges the minimum gap between electrodes, and allows replacing the 4-vane RFQ structure by the simple 4-rod one. Consequently, for keeping the RFQ length at ~4m and the warm part still compact, the RFQ-DTL and RT-SC transition energies are reduced from 3MeV and 5MeV to 1.5MeV and 3.5MeV, respectively, which indeed brings more difficulties to the beam dynamics design but helps improving the RT-CH shunt impedance.

Figure 1: A survey of $R_p$ values for RFQs [5].

From EUROTRANS to MAX, the injector design has lowered the RF power consumption per unit length and the Kilpatrick factor to ≤30kW/m and 1, respectively, for all warm cavities, even shortened the whole layout from 11.4m to 10.6m, and kept the beam dynamics performance satisfying. Being very conservative for CW operation and more cost-saving, this design has been taken as the baseline for further studies [5].

CODE BENCHMARKING
For the preliminary design of the MAX injector, the ParmteqM [6] and Lorasr [7] codes were used to simulate the beam transport in the RFQ and CH-DTL parts, respectively. Recently, the Toutatis [8] and TraceWin [8] codes have been introduced for benchmarking.

Fig. 3 shows the RFQ output beams simulated by the ParmteqM (L) and Toutatis (R) codes.

orientation, and size of the particle distributions are all quite similar on the three planes (the x and y planes are exchanged in Toutatis), respectively. Fig. 4 compares the emittance evolutions along the RFQ. Obviously, all transverse-emittance curves are almost identical, while the longitudinal-emittance ones have a small difference (which might be caused by a few halo particles) after \( z = 0.5 \text{m} \), but they have nearly same evolution shape.

Figure 4: Emittance evolutions along the RFQ.

For the CH-DTL benchmarking, the first CH cavity with the integrated two triplets (see Fig. 5) has been used.

Figure 5: Benchmarking sample from the CH-DTL.

In Fig. 6, the plots of the CH-DTL beam envelopes and output particle distributions show a good agreement between the Lorasr and TraceWin codes.

**RFQ SIMULATION WITH LEBT OUTPUT**

The MAX RFQ was designed using the New Four-Section Procedure [9] with a 4D-Waterbag input distribution. Table 1 summarizes the new simulation results based on the output particle distributions from the LEBT (Low Energy Beam Transport) designs [10]. It is seen that no matter the short or long version of LEBT will lead to similar results in the nominal (CW beam) and transient (with chopper) cases. All performance is still satisfying, except the longitudinal emittances have some relatively bigger but still acceptable growths due to the wing-form halo particles (see Fig. 7) from the LEBTs. However, the RFQ output distributions are always clean.

NEW MAX INJECTOR DESIGN

In the previous beam dynamics studies, the space needed for the inter-tank components was reserved by estimation. The inter-tank sections have been newly redesigned including all the details, e.g. the bellows for connecting cavities, the magnetic-field shielding for the solenoids, and the real dimensions of the cryomodule. The drift spaces between the cavities become longer, especially at the RFQ-DTL and RT-SC transitions, which increases the difficulty for the beam dynamics design.

The most critical area is the RT-SC transition where the drift space was extended by ~50cm. To overcome the negative consequences in both longitudinal and transverse planes, a new rebunching cavity (so-called RB-2) working at the -90° synchronous phase and a new solenoid have been added in front of the first SC-CH.

Figure 8: New layout for the MAX injector.

The beam dynamics of the new CH-DTL shown in Fig. 8 was re-optimized by tuning the focusing strength of all lenses and the gap voltages of the rebunching cavities while the design of the CH-cavities was kept almost unchanged.

Figure 8: New layout for the MAX injector.

The beam dynamics of the new CH-DTL shown in Fig. 9 plots the transverse beam envelopes along the new CH-DTL. In the first triplet, a few beam losses might happen when errors are included, but at 1.5MeV this beam energy they don’t play any role. Therefore, a large safety margin is available for the beam throughout the CH-DTL. In addition, the emittance growths are still modest, as shown in Fig. 10.

CONCLUSIONS AND OUTLOOK

The correctness of the simulation results of the MAX injector design was successfully crosschecked by different codes. It was also proven that realistic LEBT output beams accelerated by the MAX RFQ will be transported into the CH-DTL with excellent beam quality. In addition, the simulation of the new CH-DTL updated with detailed inter-tank configurations has shown good performance. To sum up, an advanced new design is now available for the MAX injector. In the next step, systematic error studies will be performed.

ACKNOWLEDGEMENTS

Special thanks go to J.-L. Biarrotte and D. Uriot for their valuable contributions to the benchmarking using the Toutatis and TraceWin codes.
