Abstract
During 2012 we have developed the system for beams separation, based on the splitter magnet, for simultaneous work of neutron source RADEX and a treatment room of the complex of proton therapy (CPT).

This setup also allows for an independent change of protons energy in the channel of proton therapy in a wide range from 209 MeV to 70 MeV.

The system is an extension of the main channel of the proton and H- beams, previously described in [1]. Main channel carries out the simultaneous transportation and elevation of the beams H- and protons in the experimental hall of INR RAS.

BEAMS SEPARATION AND UPGRADE OF THE CHANNEL TO RADEX

Figure 1 depicts the layout of the beams separation the beams line. After magnet 4MC the main beams line (protons and H-) from Linac distributes to three beam lines as shown in Fig.1. Magnet 2MC2 [1] has been replaced by a pair of magnets 4MC and 4M.

A pair of magnets of this scheme provides a correction in the position of the deflected beam at its axial passage through the hole without the field of magnet 4MC.

The poles of magnet 4MC were developed by NIIEFA as part of the design Lambertson Septum Magnet for the proton storage ring. Coil of the magnet 4MC have been manufactured from the radiation-resistant water-cooled cable of PYROTENAX type.

The block of water-cooled poles is placed in the thin walled vacuum stainless steel chamber. There are the apertures in the upper and lower poles.

Wall thickness between the aperture and the gap is about 1 mm. Detailed description of the magnet will be presented in the next paper.

Figure 2: 4MC magnet assembly view downstream.

Figure 3: 4MC magnet assembly view looking upstream.

In front of the magnet 4MC a thin foil is installed, with aperture of different diameters, to control the intensity of the beam H-. The thickness of the foil is sufficient for a recharge H- in protons. Protons from distribution tails are deflected after recharging in the BS - beam stopper.

Due to the fringe fields, especially at the exit of the magnet, the direct beam experiences a deflection on some mrad. The set of doublet lenses L31-L32 is installed in order to fix the position of the beam on the target of the neutron source RADEX. These lenses focus the centre of magnet 4MC on the target centre (Fig.4).

Detailed description of this magnet will be presented in the next paper.
Calculations showed that the coefficient of magnification in x and y at the target is 3 and 7 respectively, depending on the type of focus, eliminating the beam focus to critically small size.

Beams H and protons are displaced vertically relative to each other by 4 cm by steering magnets SM1 and SM2 (see on Fig.1), that have opposite polarity. Further inside the magnet 4MC, one beam passes through the aperture in the pole (bottom pole on Fig.3); the other is deflected by an angle of 11.5°.

The water-cooled magnetic screen is placed at the entrance of the magnet to reduce local fringe magnetic field, and to protect the iron plate septum from high intensive beam. Table 1 shows the results of the measurements of magnetic fields in the septum magnet.

**CHANNEL TO COMPLEX OF PROTON THERAPY**

The deflected beam is directed into the channels on the installation CPT or other neutron sources. Here we present the work of the channel for the CPT, whose optical scheme is changed for independent adjustment of the energy of the protons in the beam.

Channel functionally consists of two parts:
- Head channel, focusing the beam on a wedge-shaped absorber.
- Main medical channel, shaping of the beam for the treatment room of CPT.

One of the features of the main part optical scheme is the availability of considerable coefficient of the magnification at the end of the channel. This allows us to increase the number of protons after the wedge-shaped absorber by reducing the angular divergence of the particles in the channel and thus reduce the losses.

Compared to the previous scheme of the channel [4] the following changes have been implemented:
- Beam H is the basic beam of the channel.
- Control of the intensity of particles in the beam is done by recharging the beam in front of the magnet 4MC to protons, which are deflected in the opposite direction and are absorbed in a beam stopper outside the channel (Fig.1, Fig.2).
- Lenses L49-L50 and L51-L54 are included.
- Wedge-shaped beryllium degrader and tantalum collimator with diameter 4mm, have been installed.
- The tantalum aperture collimator has been installed.
- The momentum collimator has been installed.
- The second aperture collimator for halo beam absorption has been installed.

**Fig.5** shows the optical scheme of the main channel onto the installation CPT and the beam envelope.
channel (Table 2) and the main parameters of the beam in Table 3 are shown for three value of energy.

Currently the assembly and installation of the equipment is carried out in the experimental hall at INR RAS. Testing of the new channel is expected to take place in the early 2013.

ACKNOWLEDGMENT

Authors are grateful to the fund RFFI for the support of the project.
