ICFA Advanced Beam Dynamics Workshop, HB2018

June 18-22, IBS, Daejeon, Korea

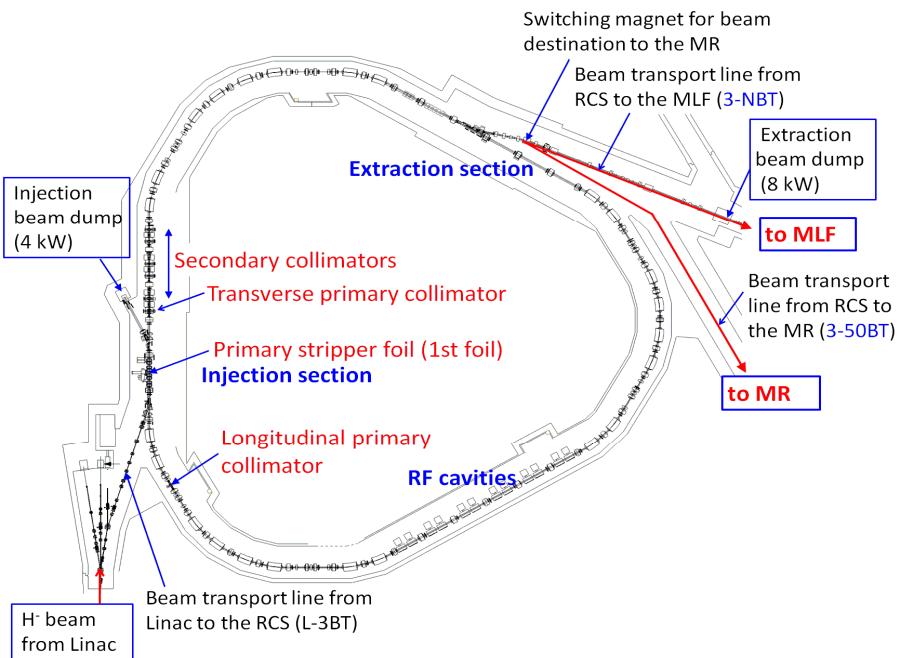

Outline:

- 1. Brief introduction of J-PARC and the RCS**
- 2. Stripper foil issues**
- 3. Principle of H^- stripping by only lasers**
- 4. Experimental strategy, expected results,
present status and schedule**
- 5. Discussion on laser energy reduction**
- 6. Summary and outlook**

J-PARC KEK & JAEA)

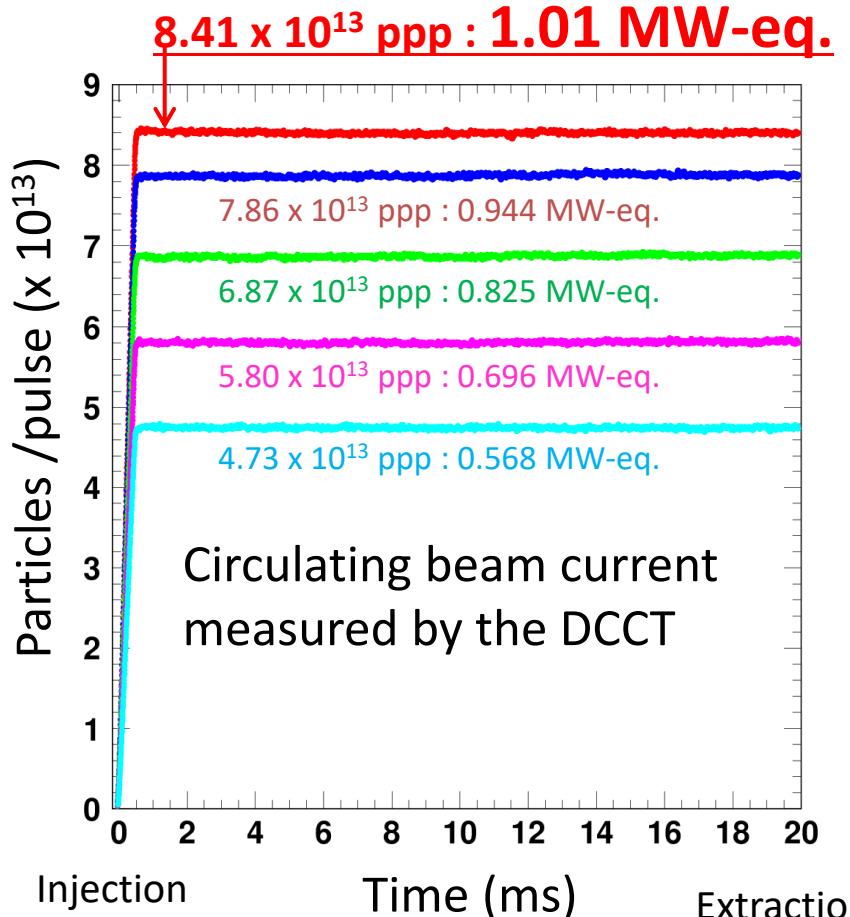

Introduction of J-PARC 3-GeV RCS

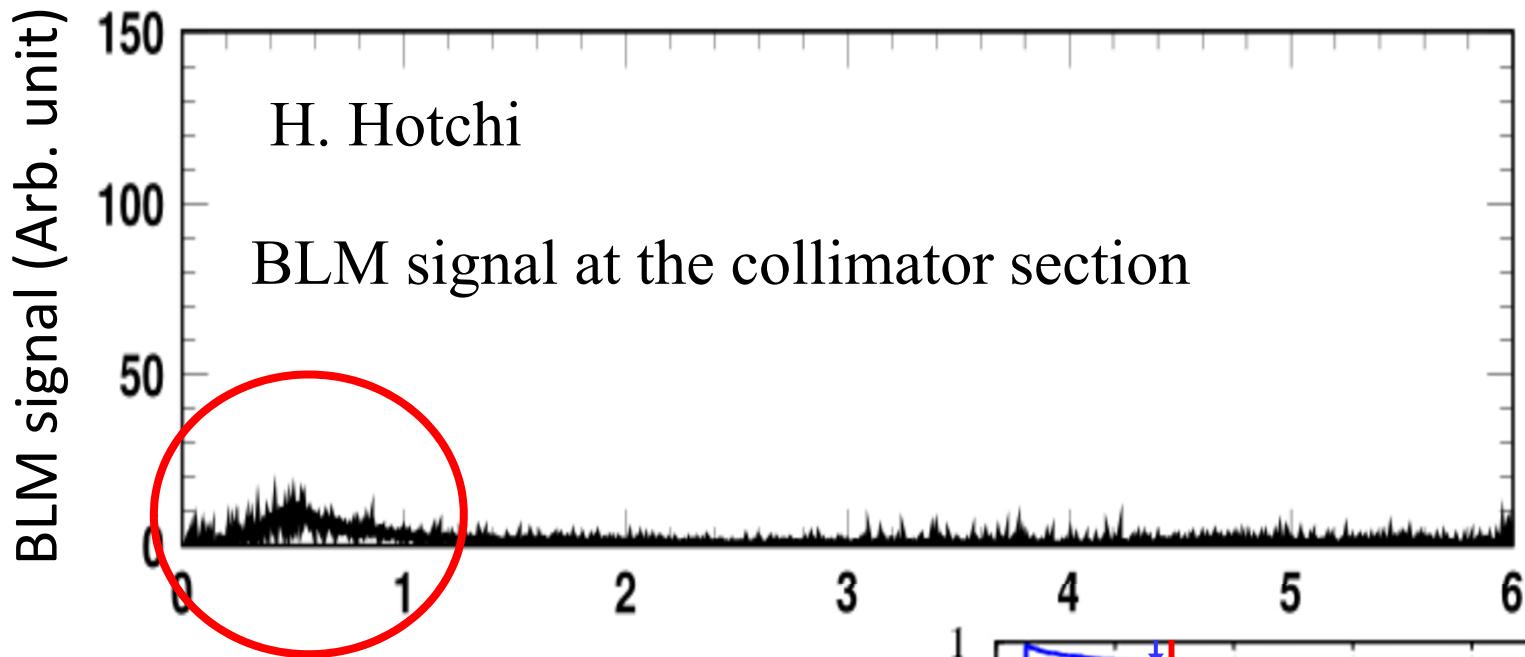

Layout of J-PARC 3-GeV Rapid Cycling Synchrotron (RCS)

- Multi-turn H^- stripping injection.
- Injection Energy: 400 MeV
- Extraction Energy: 3 GeV
- Repetition: 25 Hz
- **Beam power (design): 1MW**

→ Successfully demonstrated acceleration of the designed beam intensity.

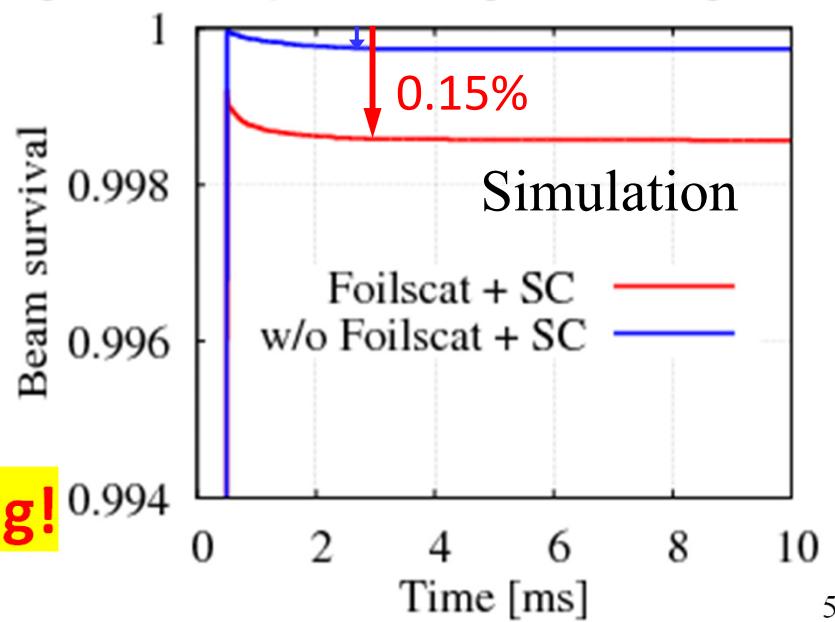

Beam loss at 1 MW beam power

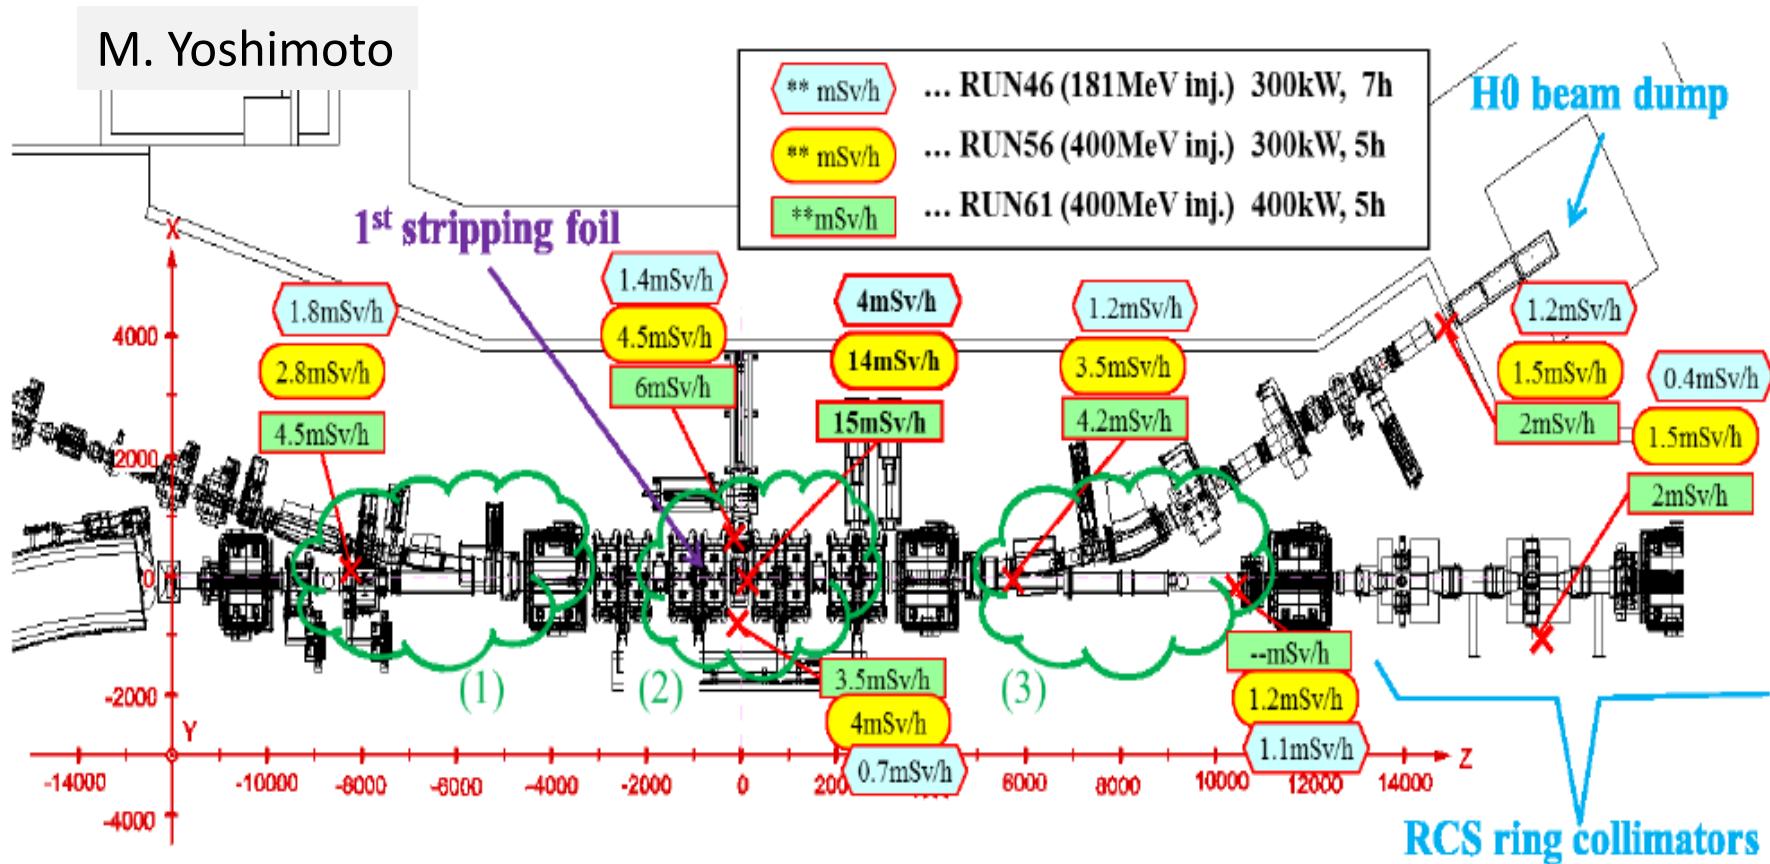

- Beam loss at 1 MW: $\sim 0.2\%$ and localized at collimator section (**<< 3% of collimator limit**)

- Beam loss occurs mainly at injection energy

→ mostly due to the foil scattering!

Residual radiation at the RCS injection area

Residual radiation near the stripper foil is as high as **15 mSv/h** on contact, 4 hours after 0.4 MW routine operation!

Experience of stripper foil behaviors at the SNS and J-PARC

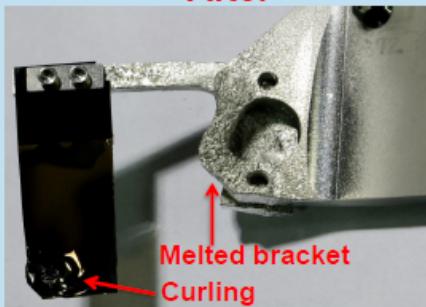

S. Cousineau (HB2014)

2014 SNS foil: 3 months in 1 – 1.4 MW beam

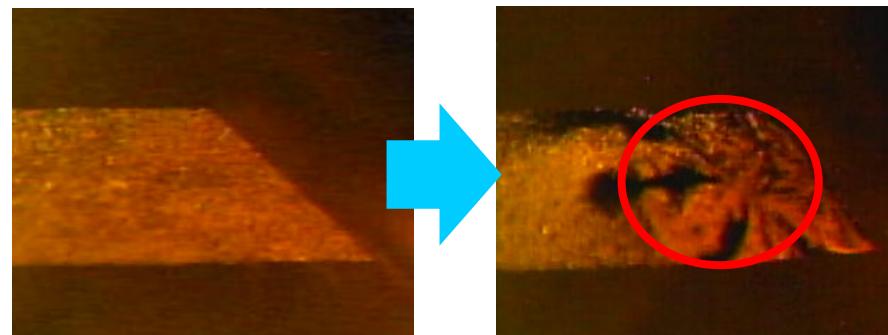

Before

After

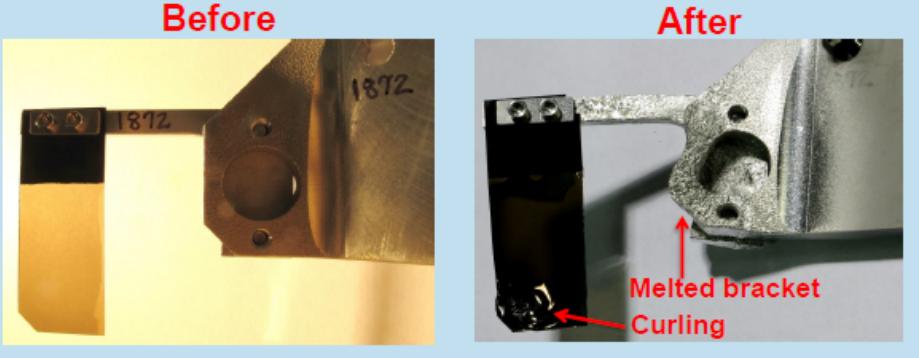

J-PARC: 0.3 MW operation
Avg. foil hit: 10

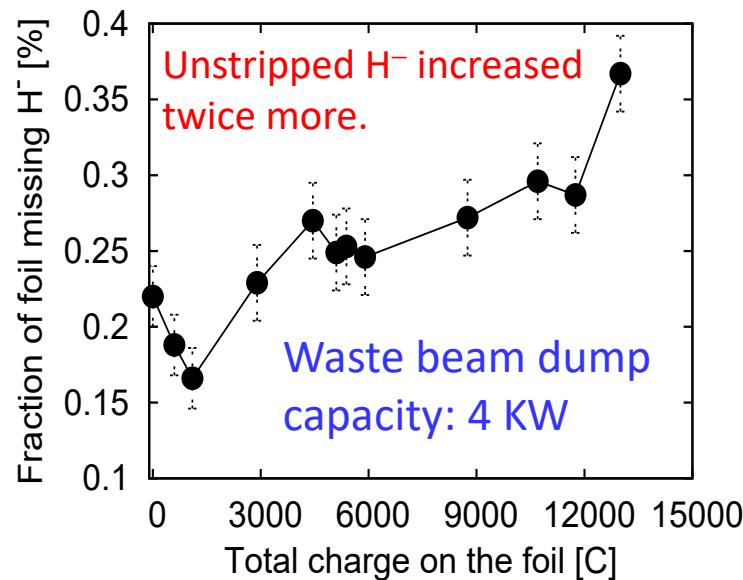

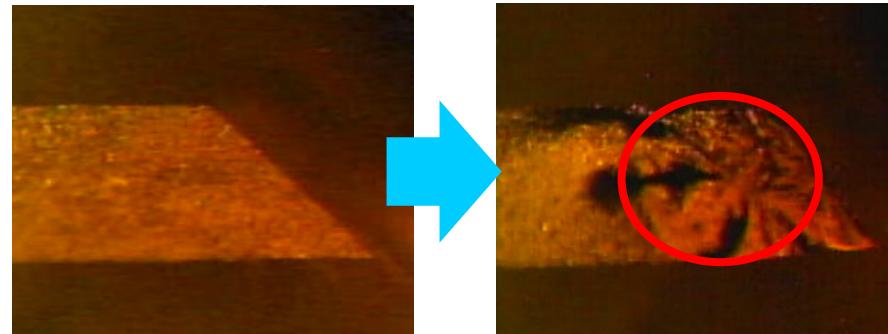

Experience of stripper foil behaviors at the SNS and J-PARC

S. Cousineau (HB2014)

2014 SNS foil: 3 months in 1 – 1.4 MW beam

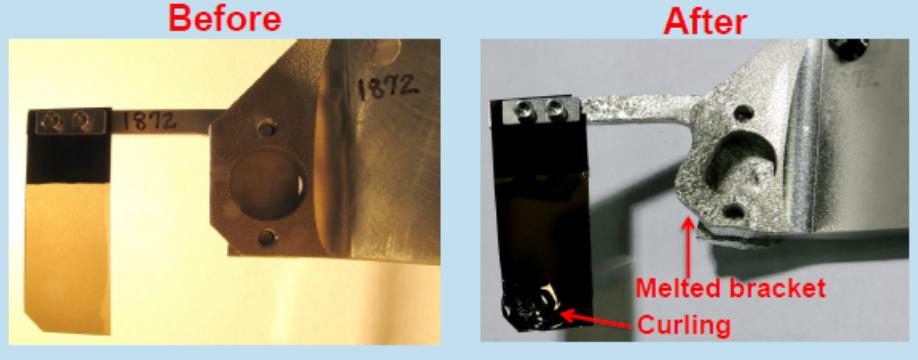

J-PARC: 0.3 MW operation
Avg. foil hit: 10

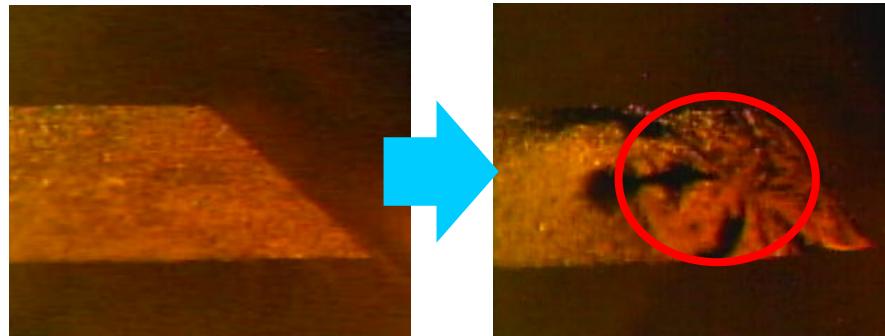

Experience of stripper foil behaviors at the SNS and J-PARC

S. Cousineau (HB2014)

2014 SNS foil: 3 months in 1 – 1.4 MW beam

J-PARC: 0.3 MW operation
Avg. foil hit: 10

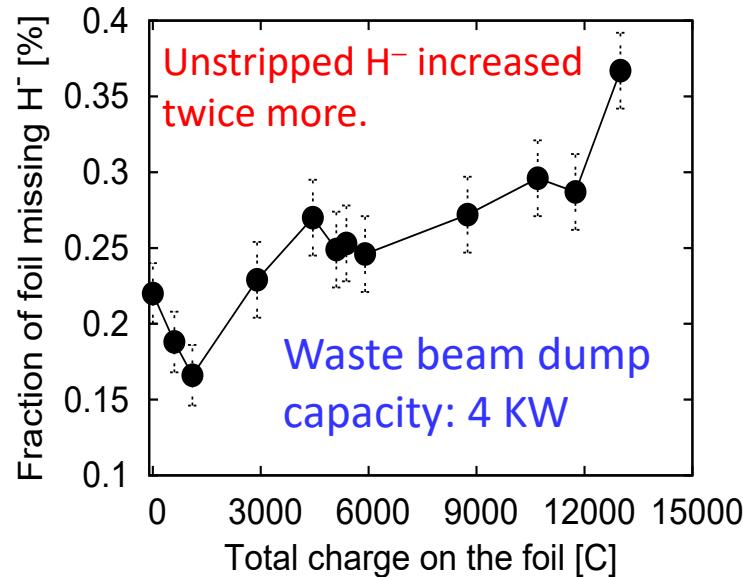

Foil hit at 1 MW operation (estimation)

To	P _{beam} (MW)	Beam sharing(%)	$\epsilon_{\text{painting}}$ ($\pi \text{ mm mrad}$)	Foil hit
MLF	1	84	200	10
MR	1	16	50	70

Normalized avg. foil hit: ~20 but
instantaneous foil heat for MR cycle is extremely high!
If the total charge limit on foil is 10000 C

→ **Foil lifetime at 1 MW: 2 weeks!**

RCS beam power at present and upgrade plan

RCS beam power to date:

To MLF: 500 kW

To MR: > 750 kW-eq.

Beam power to the MLF
will be gradually increased
to the designed **1 MW**.

RCS beam power at present and upgrade plan

RCS beam power to date:

To MLF: 500 kW

To MR: > 750 kW-eq.

Beam power to the MLF
will be gradually increased
to the designed **1 MW**.

To cope with upgrades/demands
of the downstream facilities,
RCS mid-term beam power upgrade
is set at **1.5 MW!**

RCS beam power at present and upgrade plan

RCS beam power to date:

To MLF: 500 kW

To MR: > 750 kW-eq.

Beam power to the MLF
will be gradually increased
to the designed **1 MW**.

To cope with upgrades/demands
of the downstream facilities,
RCS mid-term beam power upgrade
is set at **1.5 MW!**

***Lifetime of the stripper foil may
be the most serious issue!***

- *Foil may not survive at 1.5 MW beam power.*

- Laser stripping of H⁻ holds the promise of eliminating the limitation and issues involved with using the stripper foil.
- We aim to establish the method even at 400 MeV H- energy.

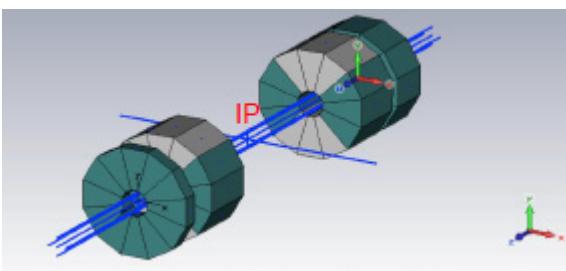

Difficulties of laser assisted H⁻ stripping at 400 MeV

Step 1:
Lorentz stripping
 $H^- \rightarrow H^0 + e^-$

Step 2:
Excitation by Laser
 $H^0 + \gamma \rightarrow H^{0*} \text{ (n}\geq 3\text{)}$

Step 3:
Lorentz stripping
 $H^{0*} \rightarrow p + e^-$

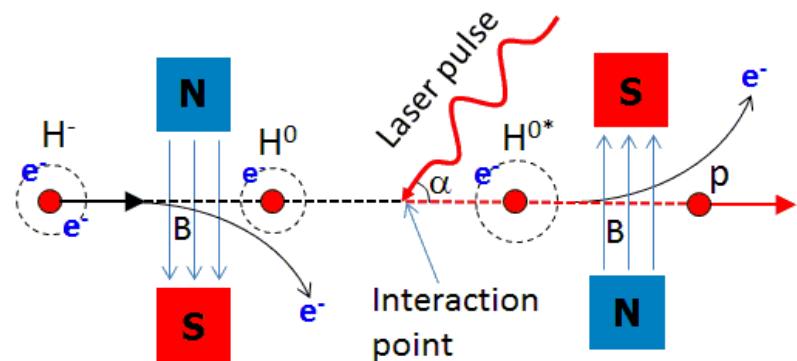

A. Aleksandrov, HB2014
For SNS 1 GeV H⁻: B=1.2T
Inner radius: 15 mm

Magnetic field issues:

- In the practical application, the magnets should have larger radius.
- For 400 MeV H⁻, hard to realize over 2 T magnetic field.
- Circulating beam size after injection is quite big!
 $r \sim 5 \text{ cm!}$

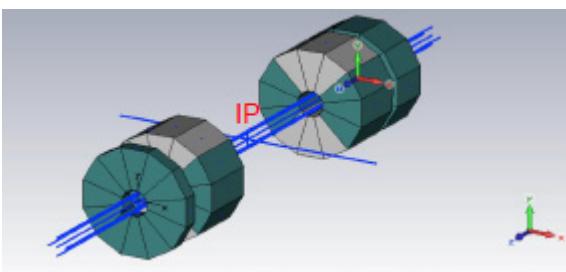

Difficulties of laser assisted H⁻ stripping at 400 MeV

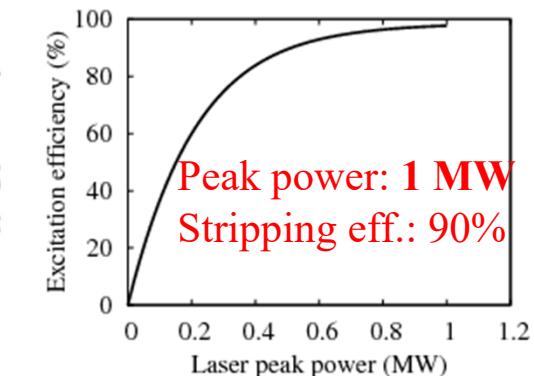

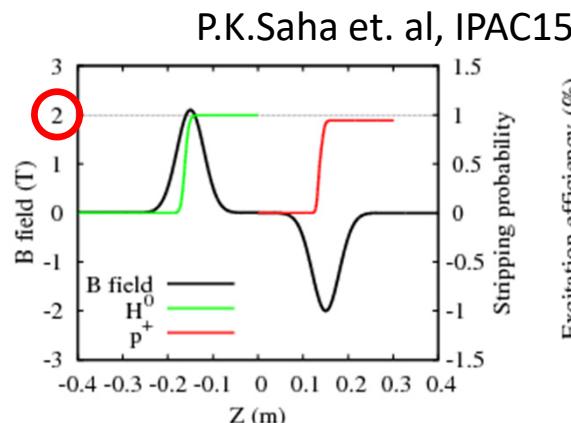

Step 1:
Lorentz stripping
 $H^- \rightarrow H^0 + e^-$

Step 2:
Excitation by Laser
 $H^0 + \gamma \rightarrow H^{0*} \quad (n \geq 3)$

Step 3:
Lorentz stripping
 $H^{0*} \rightarrow p + e^-$

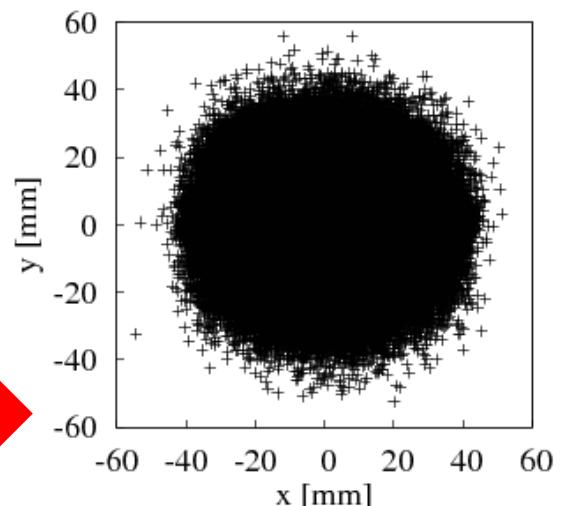

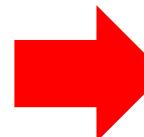

A. Aleksandrov, HB2014

J-PARC RCS: 400 MeV inj. for 1 MW
Trans. dist. at the end of injection.
(Simulation: TP: none, LP: full)

One should concern about the emittance growth and also the lifetime of H^{0*} (~5ns).

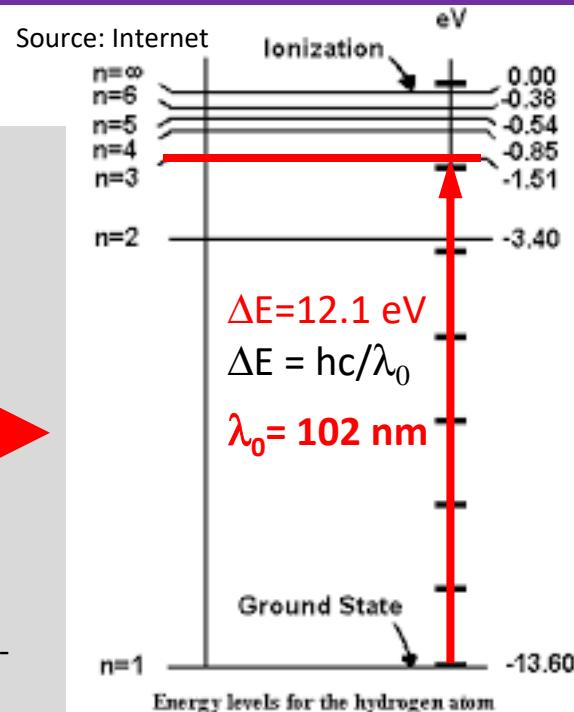

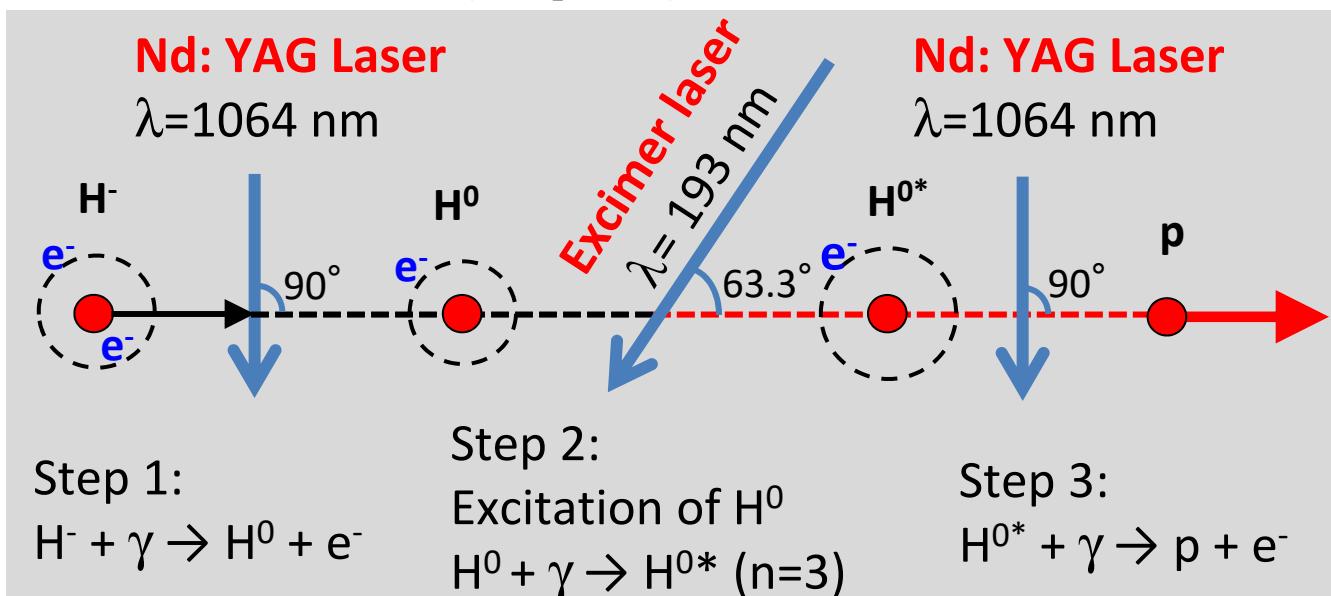

Principle of H⁻ stripping by using only lasers at J-PARC

Process	E _{ph} (eV)	λ (nm)	α (deg.)	λ ₀ (nm)	Laser
H ⁻ → H ⁰	1.67	1064	90	743	Nd:YAG
H ⁰ → H ^{0*}	12.1	193	63	102	Excimer (ArF)
H ^{0*} → p	1.67	1064	90	743	ND:YAG

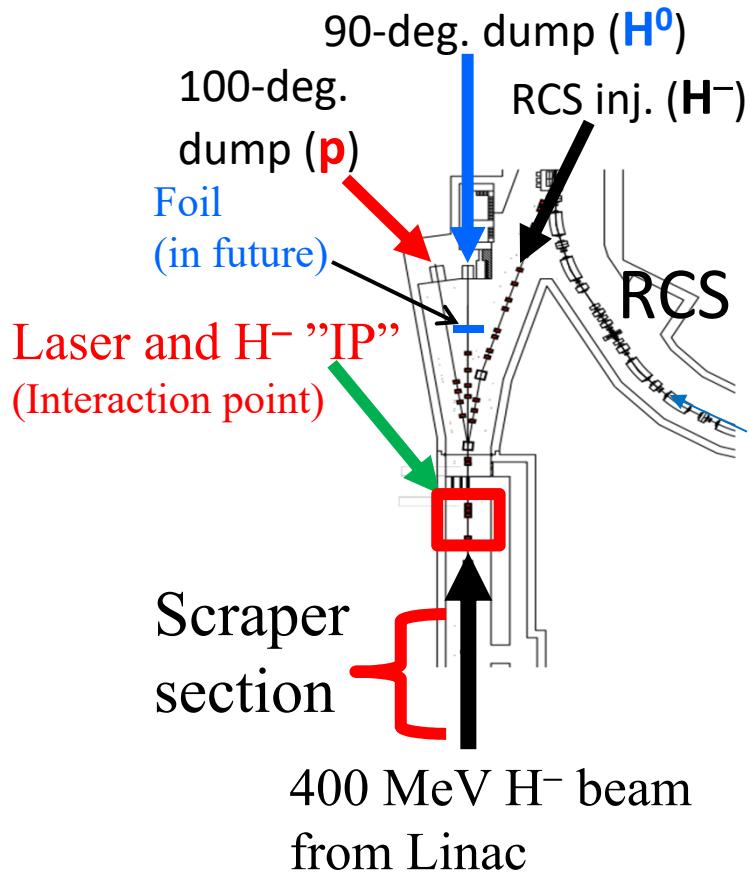

Doppler effect of the 400 MeV H⁻ beam:
 $\beta = 0.713, \gamma = 1.426$
 $\lambda = \lambda_0 (1 + \beta \cos\alpha)\gamma$

Experimental area, beamline

- The POP demonstration will be performed at the end section of J-PARC L-3BT straight section.
- The place is just downstream of the charge-exchange type beam halo scrappers.

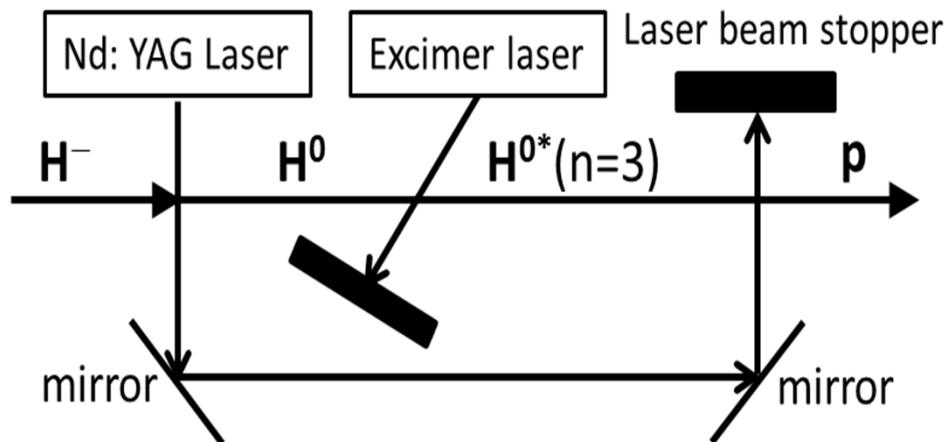

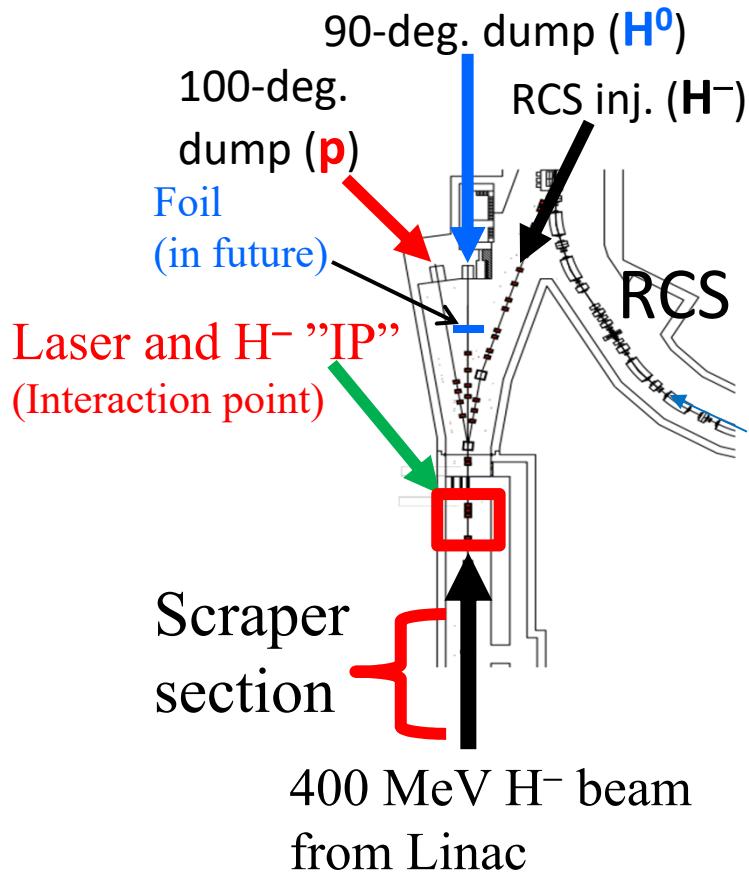

Experimental Setup and strategy

- All three charge fractions can be measured in the downstream of IP.
- We will installed a foil at the 90-deg dump to strip H^0 to p for measuring.

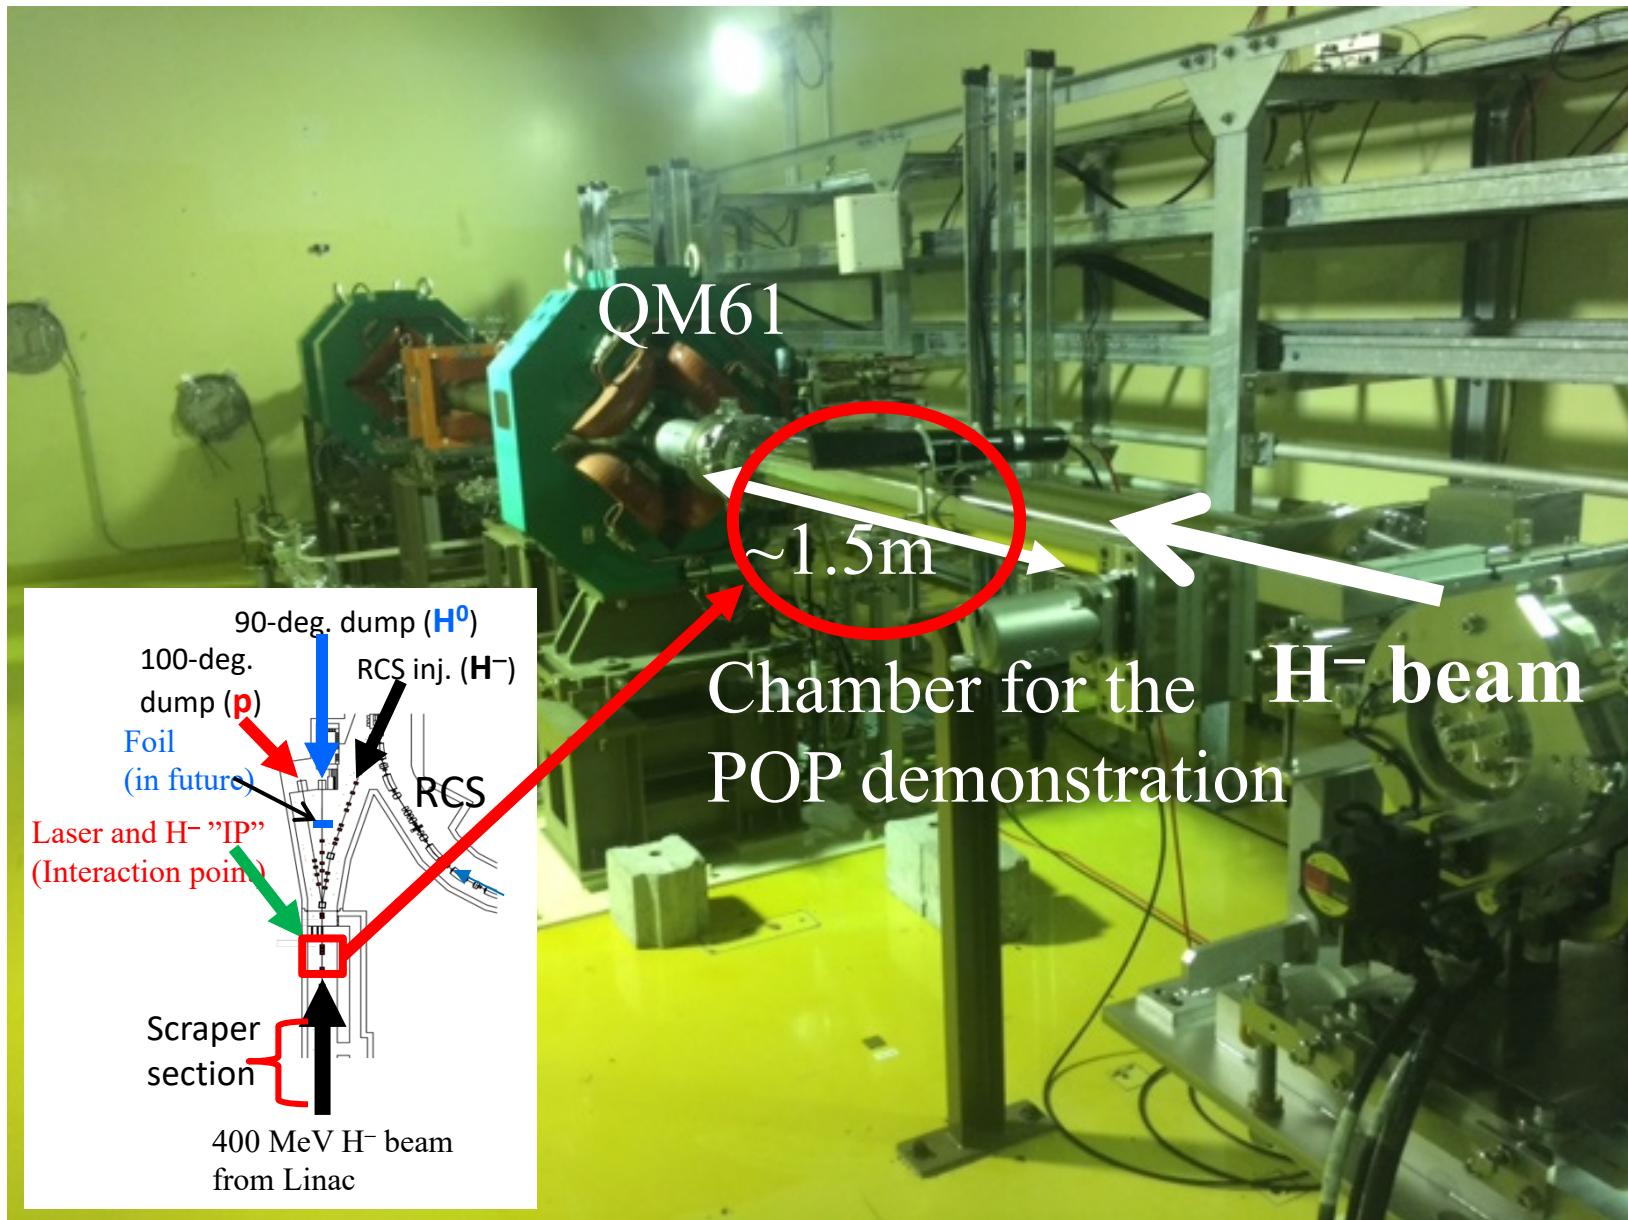

Experimental Setup and strategy

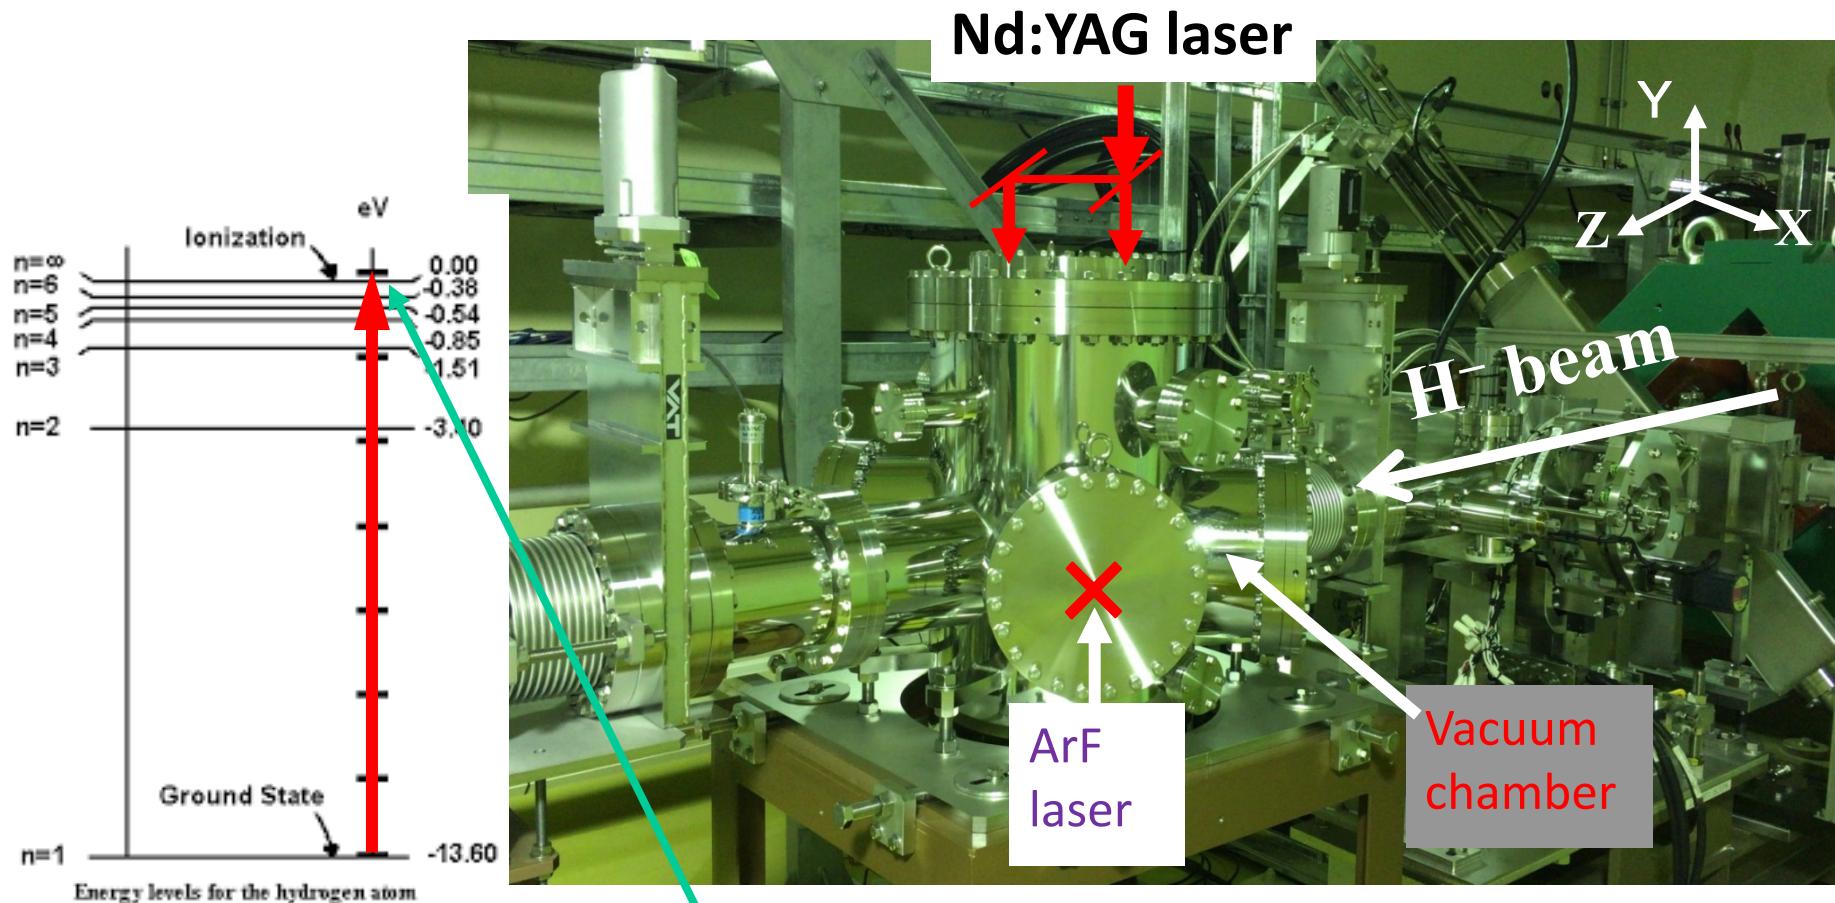

Setup for the POP experiment

- All three charge fractions can be measured in the downstream of IP.
- We will installed a foil at the 90-deg dump to strip H^0 to p for measuring.

Beam line close view

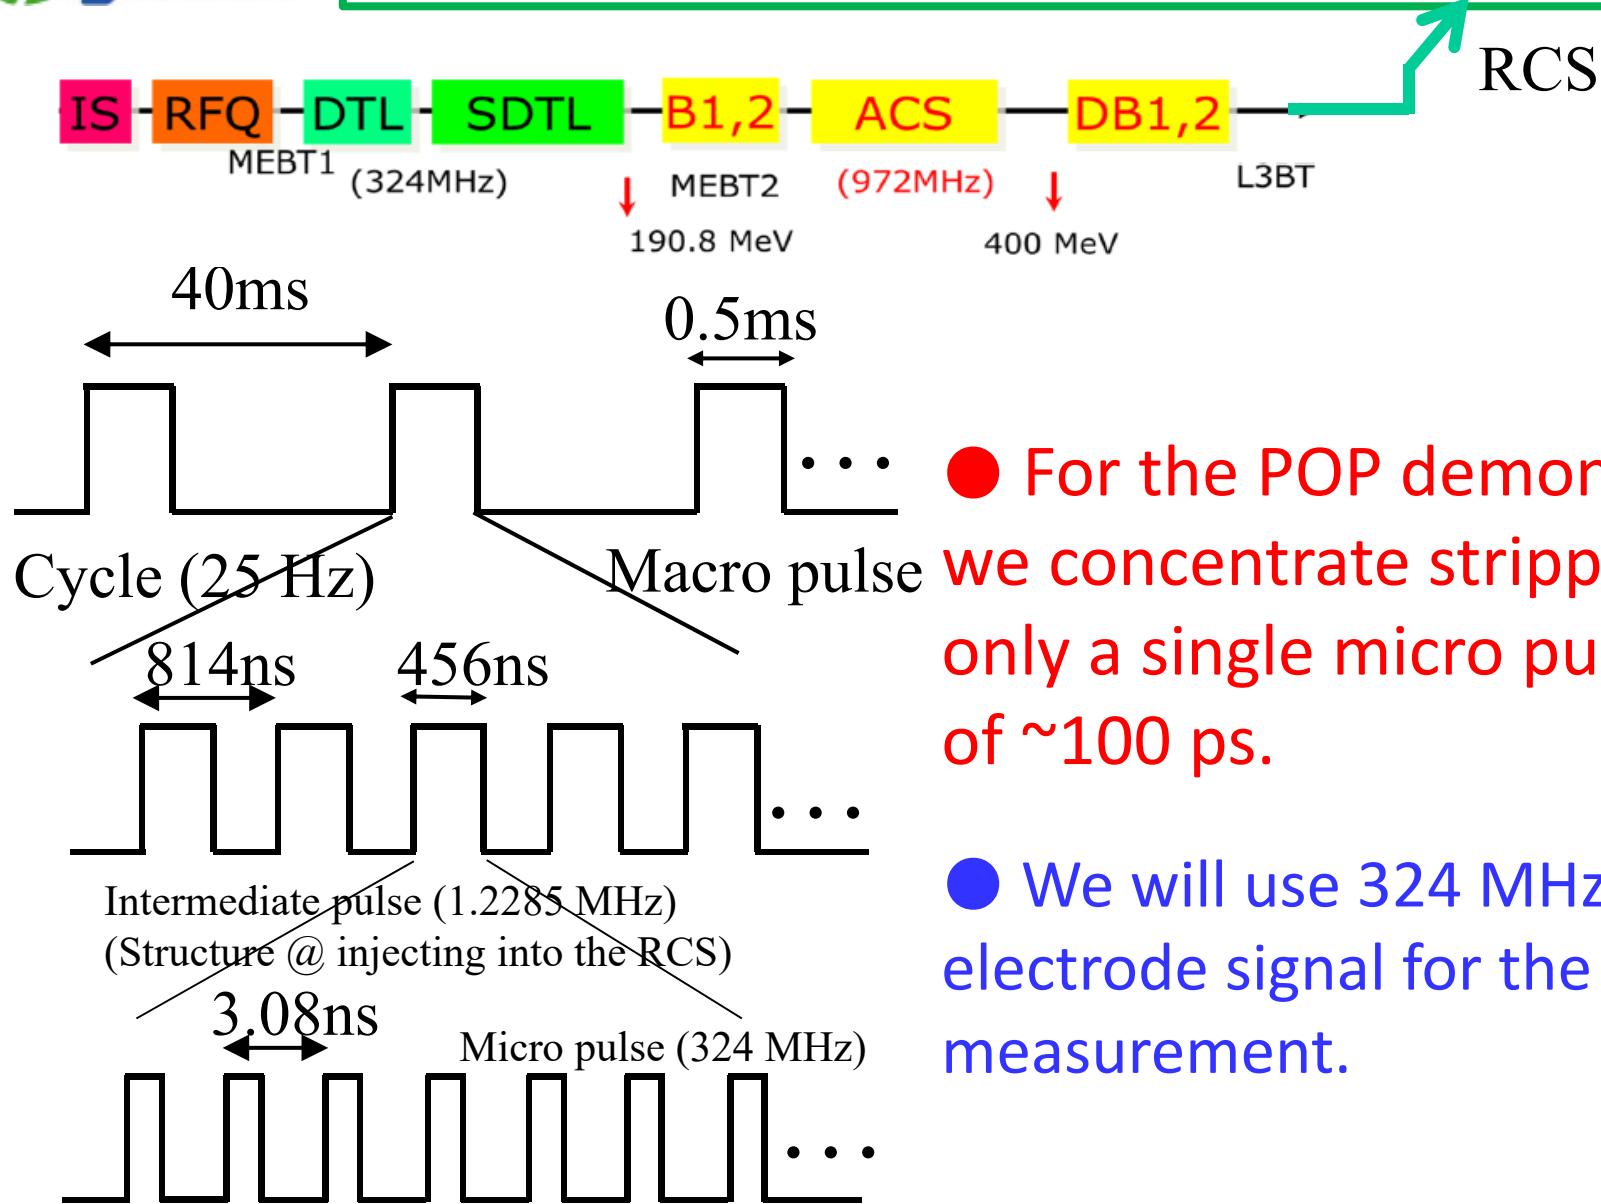

Vacuum chamber for the POP demonstration ---- Installed

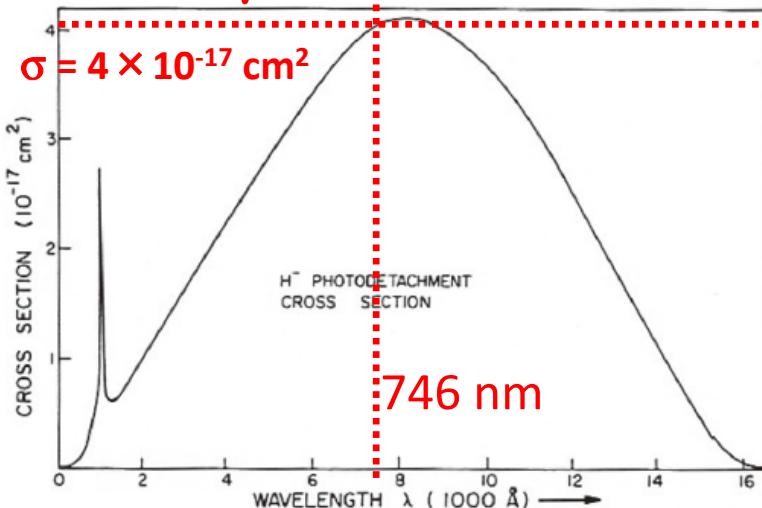

Excimer laser window size: Big enough for angle variation $67^\circ < \alpha < 45^\circ$
 → Try ionization of H0. **$\alpha = 47^\circ, \lambda_0 = 91.2 \text{ nm}$** $[\lambda = \lambda_0(1 + \beta \cos\alpha)\gamma]$

LI beam structure and Measurement strategy

Estimated Laser energy for stripping a micro pulse

Photo-detachment:

$$E_{\text{ph}} = 1.67 \text{ eV}, \lambda_0 = 746 \text{ nm}$$

Saturation density Φ^s in PRF

$$\Phi^s = (E_{\text{ph}}/\sigma) = 6.7 \times 10^{-3} \text{ J/cm}^2$$

$$r(\text{H}^-) = 2\text{mm}, t(\text{H}^-) = 100 \text{ ps}$$

$$t_i(\text{collision}) = 20 \text{ ps}, t_i(\text{laser}) = (100+20) \text{ 120ps}$$

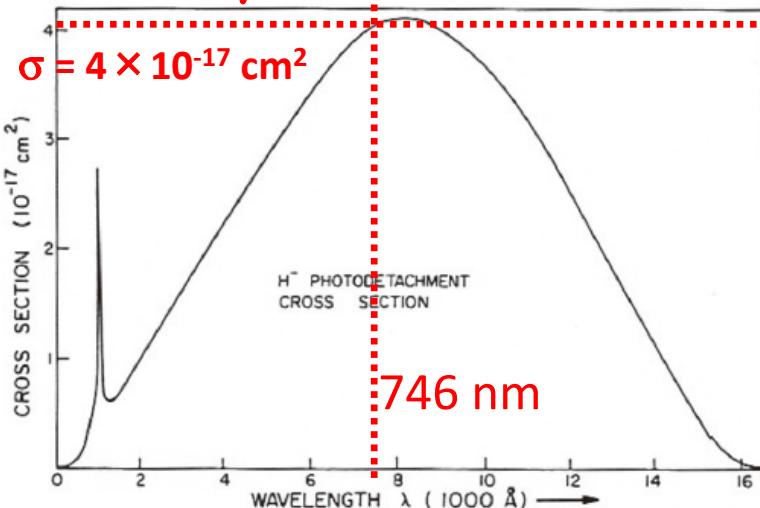

$$E(\text{laser}) = (\Phi^s/\gamma) \times (\pi r^2) \times (t_l/t_i)$$

$$= 3.5 \text{ mJ}$$

SNS, Oak Ridge

First Demonstration of Laser-Assisted Charge Excitation for Microsecond Duration H⁻ Beams

Laser pulse and peak power:

Nd:YAG laser of 1064 nm

→ 3rd hc (355 nm)

Synchronized to 402.5 MHz

H⁻ pulses.

Laser pulse: 50 μJ, 50ps

→ Ppeak: **1 MW**

Lasers we have and expected stripping efficiency for the POP demonstration

1. YAG laser (1064 nm pulsed)

$E = 0.2 \sim 0.6 \text{ J}$, $5 \sim 10 \text{ ns}$ (FWHM)

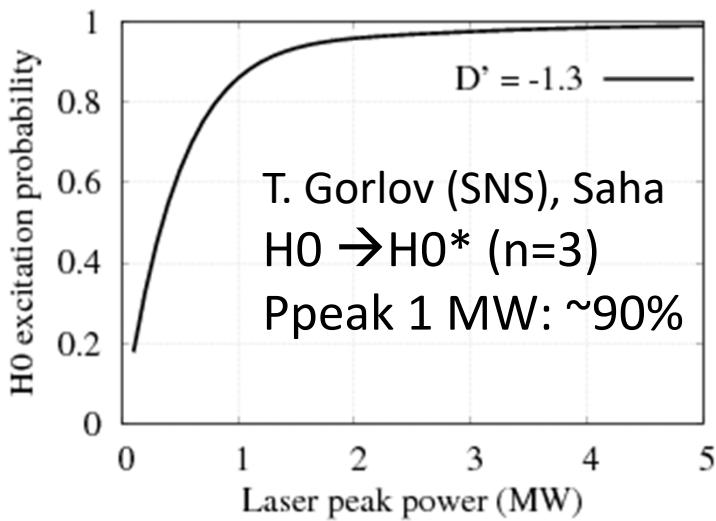

2. ArF Excimer laser (193 nm pulsed)

ArF 193 nm excimer laser (by Mlase)

$E = 13 \text{ mJ}$, Pulse length = 5-10 ns (σ)

Bandwidth: $\sim 4\text{THz}$

→ $P_{\text{peak}} > 1 \text{ MW}$ can be reached

Typical 324 MHz BPM electrode signal.
The red curve is an expected change of the H^- signal (black) due to its stripping to p.

We expect 90% stripping eff for at least one micro pulse which matches at the center of the laser pulses.

Manipulation of H⁻ beam for reducing the laser power

Extensive manipulations of the H⁻ beam are very important to reduce the laser power, especially for the Excimer laser.

For us, the order might be as follows:

- ★ Dispersion derivative of the H⁻ beam
- ★ Minimization of the betatron angular spread
- ★ Shorter longitudinal beam size. $\sigma_z < 100$ ps

.....

Dispersion derivative and minimize betatron angular spread to reduce the laser energy

Required maximum angular spread $(\Delta\alpha_l)_m$ of the laser pulse to cover ion beam (Ref: I. Yamane)

$$(\Delta\alpha_l)_m = \left(\frac{\beta(\beta + \cos\alpha)}{1 + \beta\cos\alpha} \left(\frac{\Delta p}{p} \right) + \frac{\beta\sin\alpha}{1 + \beta\cos\alpha} (\Delta\theta)_m \right) \times \frac{1 + \beta\cos\alpha}{\beta\sin\alpha}$$

Dispersion derivative and minimize betatron angular spread to reduce the laser energy

Required maximum angular spread $(\Delta\alpha_l)_m$ of the laser pulse to cover ion beam (Ref: I. Yamane)

$$(\Delta\alpha_l)_m = \left(\frac{\beta(\beta + \cos\alpha)}{1 + \beta\cos\alpha} \left(\frac{\Delta p}{p} \right) + \frac{\beta\sin\alpha}{1 + \beta\cos\alpha} (\Delta\theta)_m \right) \times \frac{1 + \beta\cos\alpha}{\beta\sin\alpha}$$

Utilize dispersion derivative

V. Danilov, PRST-AB, 2003

Eliminate transition frequency spread

Required maximum angular spread $(\Delta\alpha_l)_m$ of the laser pulse to cover ion beam (Ref: I. Yamane)

$$(\Delta\alpha_l)_m = \left(\frac{\beta(\beta + \cos\alpha)}{1 + \beta\cos\alpha} \left(\frac{\Delta p}{p} \right) + \frac{\beta\sin\alpha}{1 + \beta\cos\alpha} (\Delta\theta)_m \right) \times \frac{1 + \beta\cos\alpha}{\beta\sin\alpha}$$

Utilize dispersion derivative

V. Danilov, PRST-AB, 2003

Eliminate transition frequency spread

$$D' = -\frac{\beta + \cos\alpha}{\sin\alpha} = -1.3$$

- Hydrogen atom with different energies have the same laser light frequency in their rest frame.
 - Uniform laser beam.
- Gain on the laser peak power.

Dispersion derivative and minimize betatron angular spread to reduce the laser energy

Required maximum angular spread $(\Delta\alpha_l)_m$ of the laser pulse to cover ion beam (Ref: I. Yamane)

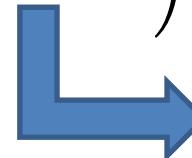

$$(\Delta\alpha_l)_m = \left(\frac{\beta(\beta + \cos\alpha)}{1 + \beta\cos\alpha} \left(\frac{\Delta p}{p} \right) + \frac{\beta\sin\alpha}{1 + \beta\cos\alpha} (\Delta\theta)_m \right) \times \frac{1 + \beta\cos\alpha}{\beta\sin\alpha}$$

Utilize dispersion derivative

Reduce betatron angular spread

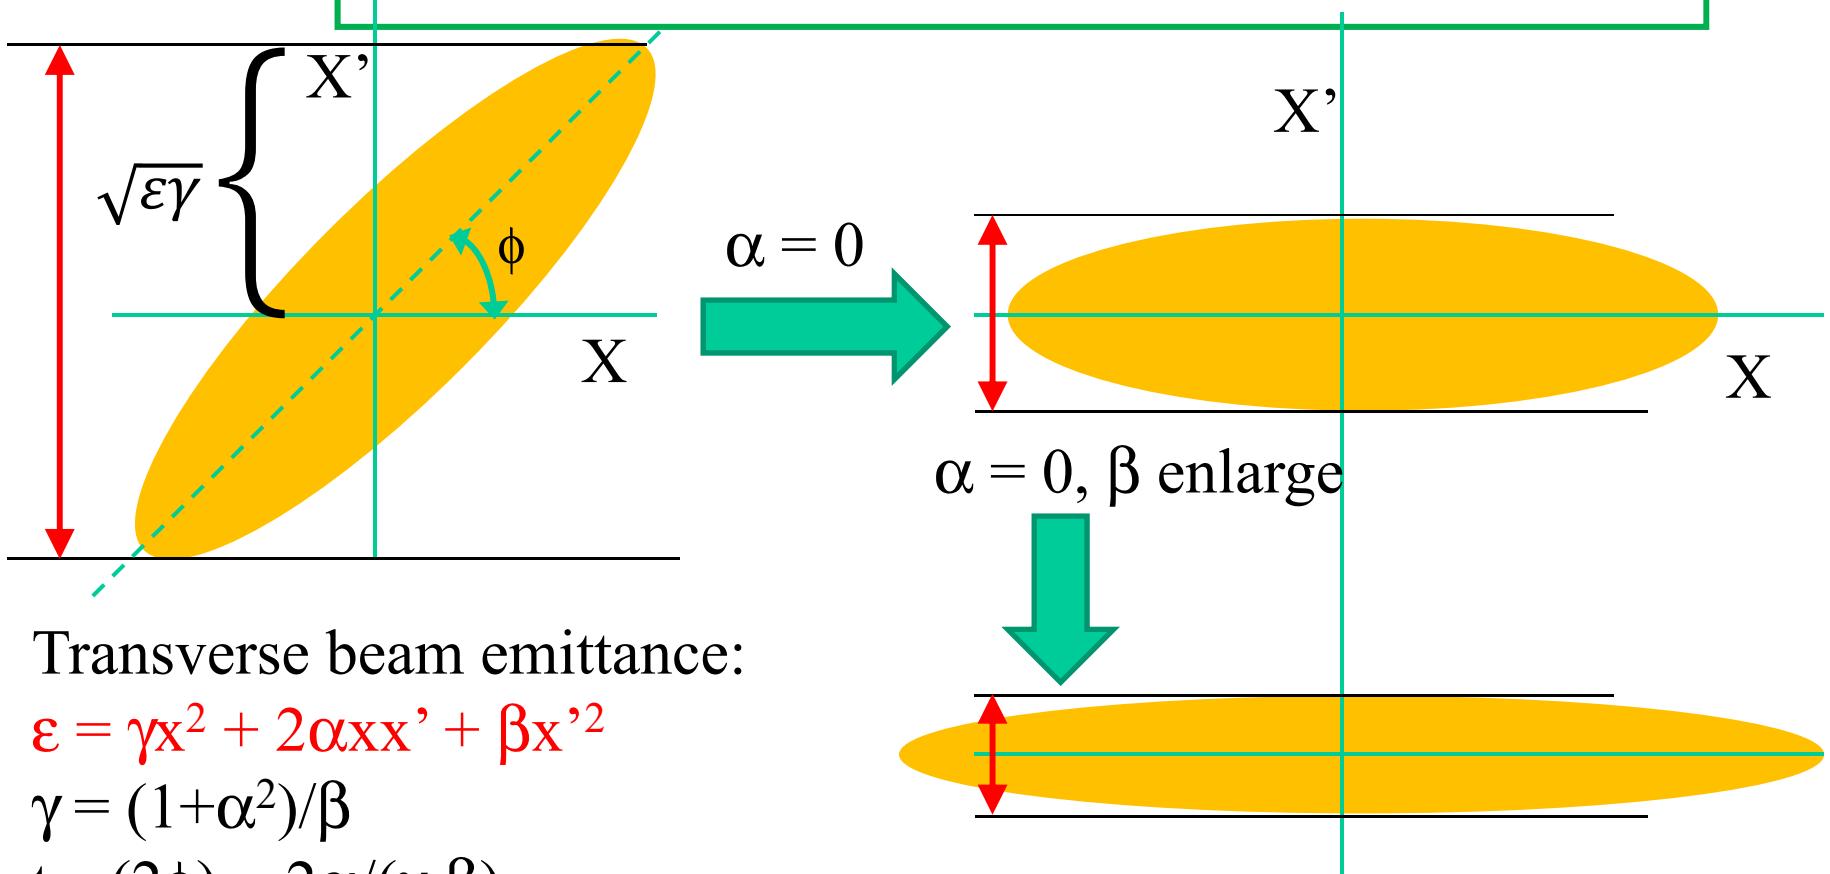

Eliminate transition frequency spread

$$D' = -\frac{\beta + \cos\alpha}{\sin\alpha} = -1.3$$

- Hydrogen atom with different energies have the same laser light frequency in their rest frame.
 - Uniform laser beam.
- Gain on the laser peak power.

Minimization of betatron angular spread

Transverse beam emittance:

$$\epsilon = \gamma x^2 + 2\alpha x x' + \beta x'^2$$

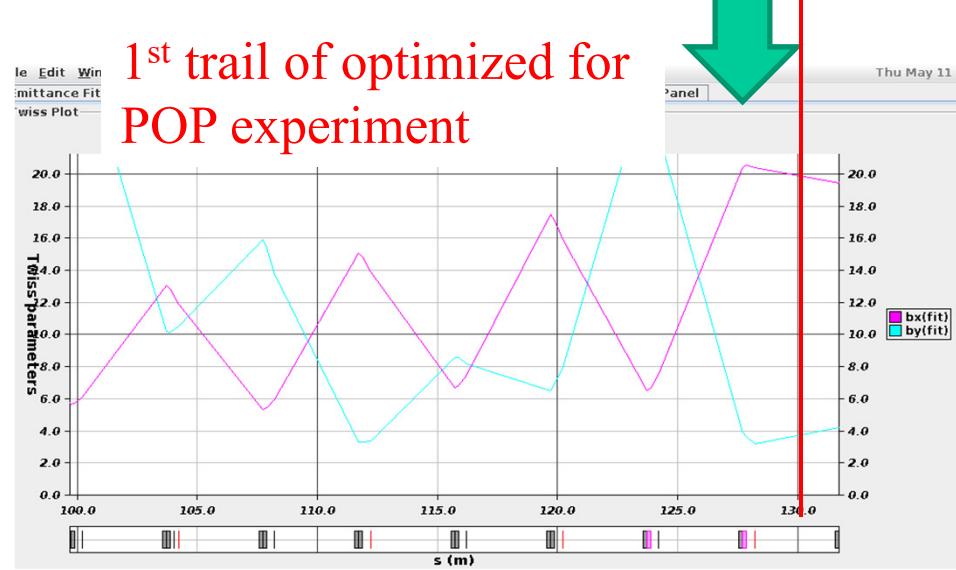

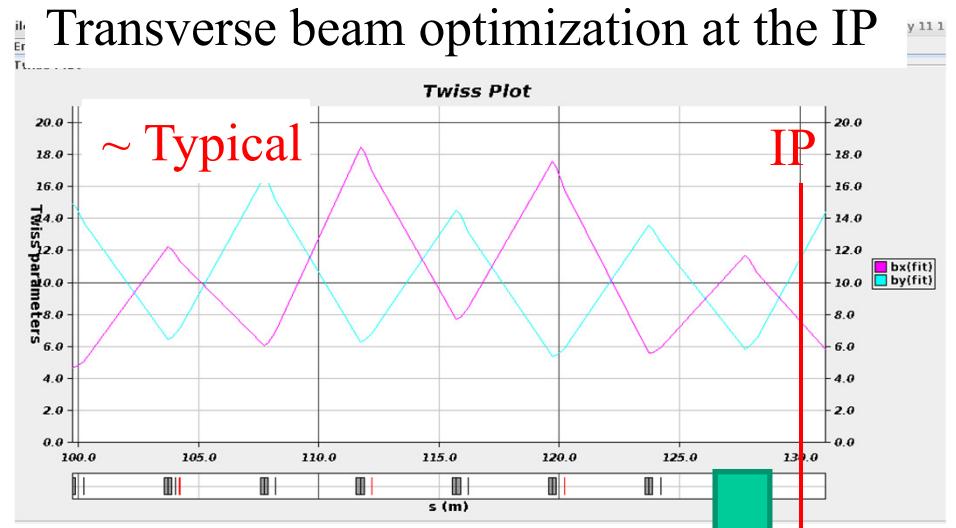

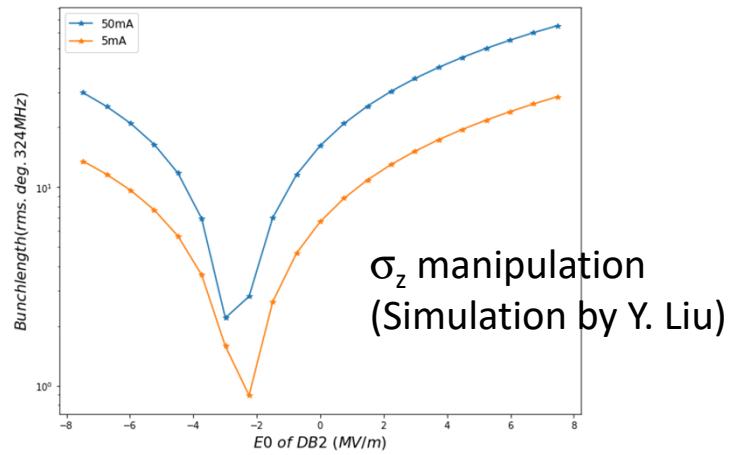

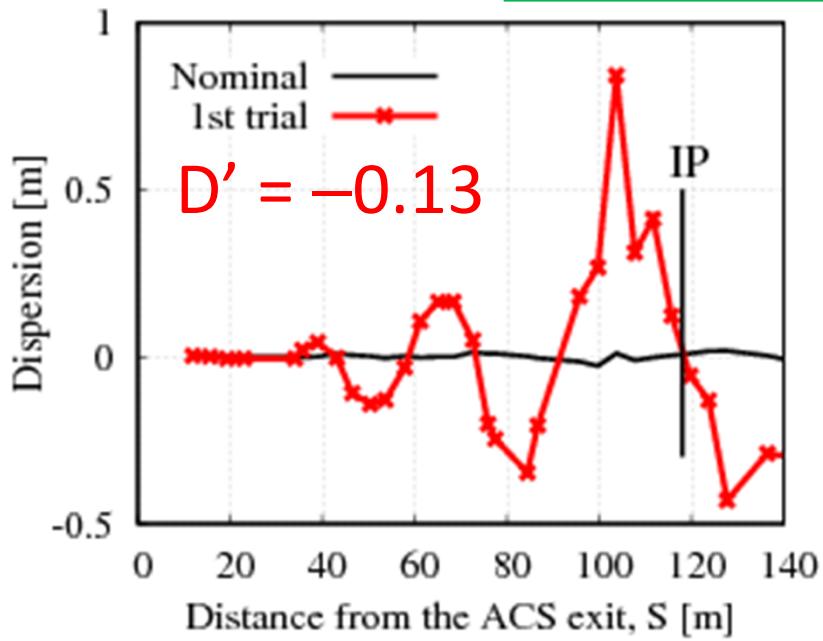

$$\gamma = (1+\alpha^2)/\beta$$

$$\tan(2\phi) = 2\alpha/(\gamma - \beta)$$

$\alpha, \beta, \gamma, \epsilon$ are called twiss parameters

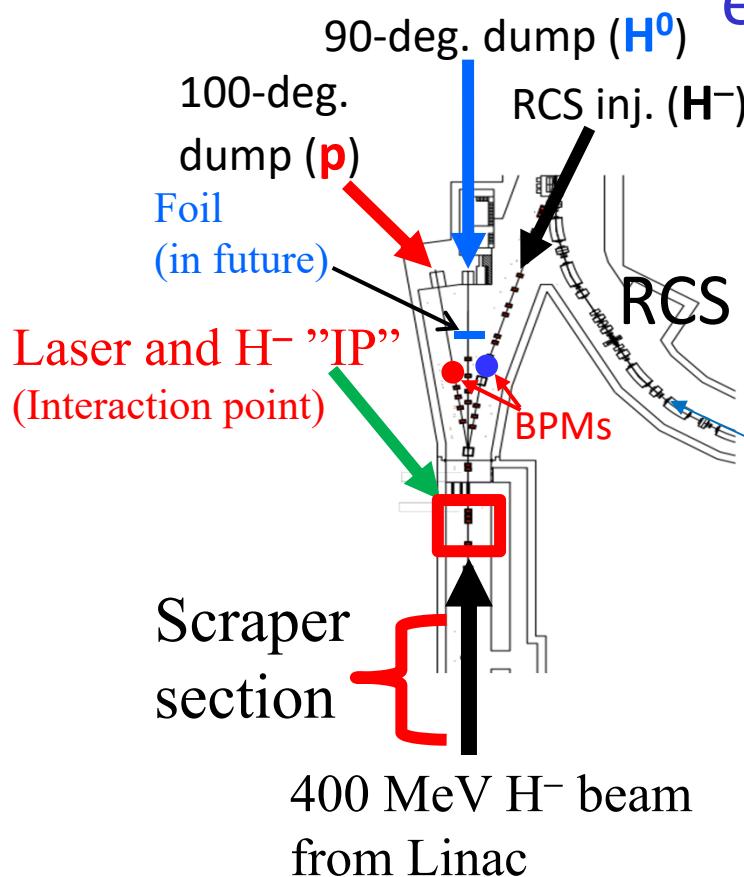

Angular spread is controlled by optimizing α to zero and also with large β .

Trial manipulation of the H⁻ beam

Further studies are planned

Measurement method of stripping efficiency of a single micro pulse

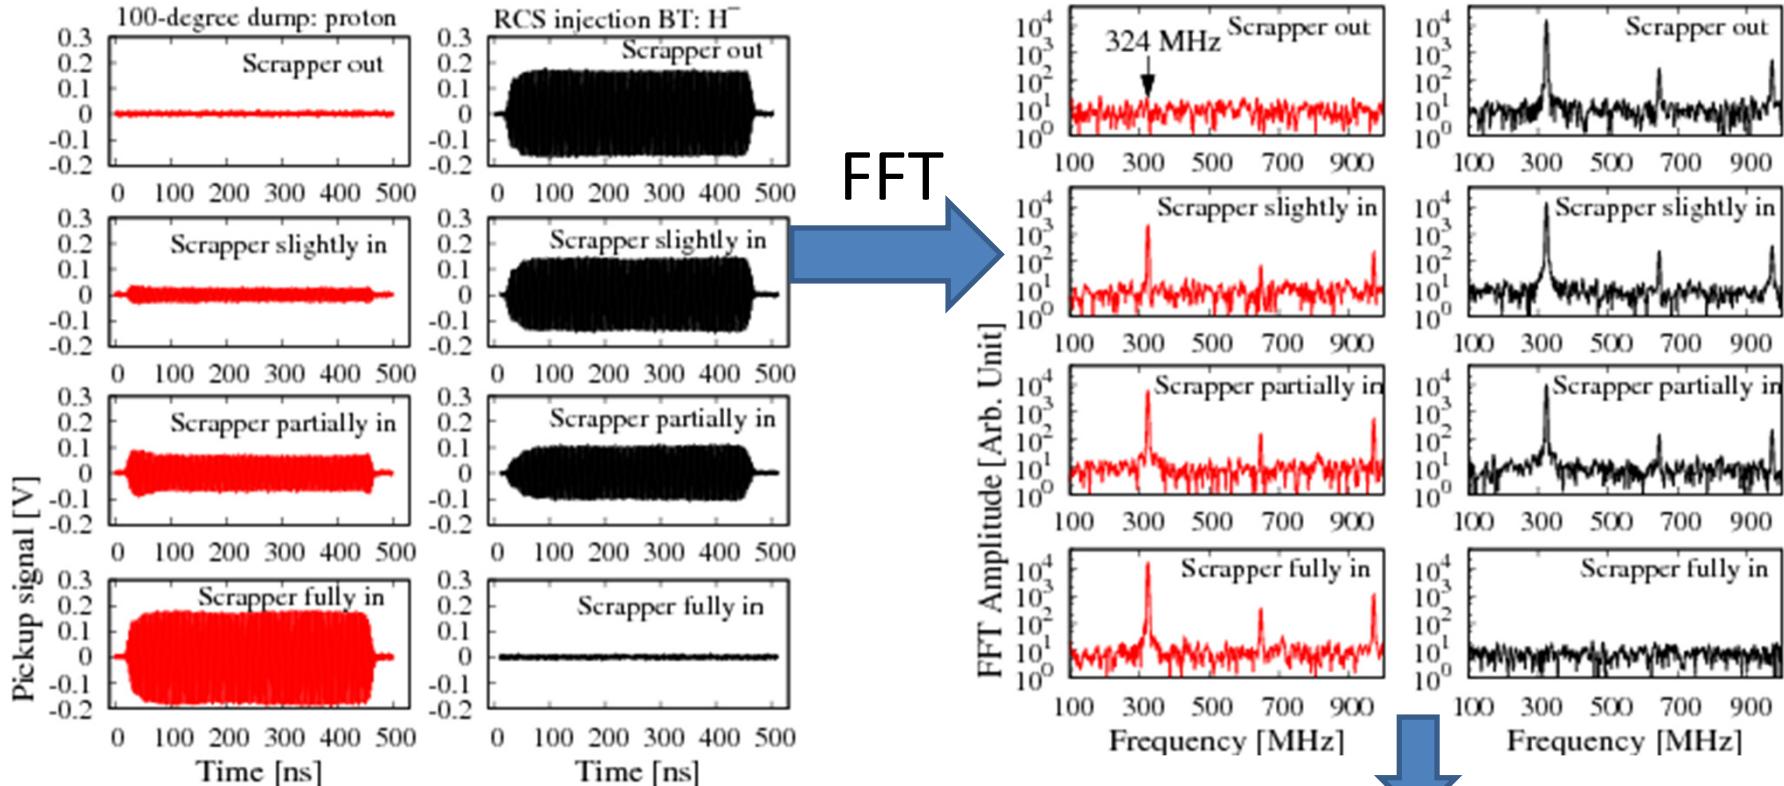

Scraper & Beam	To 100-deg. Dump (p)	To 90-deg. Dump (H^0)	To RCS (H^-)
Scraper OUT	---	---	H^- 100%
Half IN	p 49.999%	$1 \times 10^{-3} \%$	H^- 50%
Fully IN	p 99.998%	$2 \times 10^{-3} \%$	$< 10^{-10} \%$

Checked by inserting L-3BT scraper at present

(Charge-exchange type transverse beam halo scrapper. Stripped protons go to the 100-deg. beam dump)

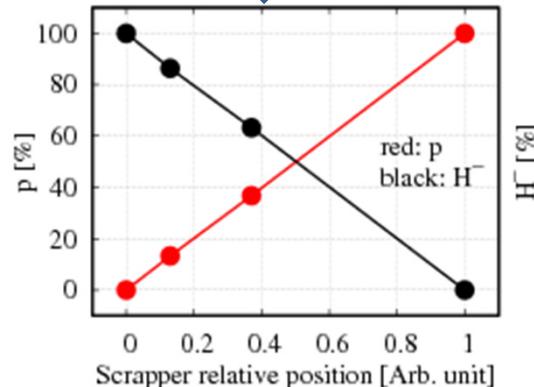

The 324 MHz BPMs electrode data was taken by a fast oscilloscope.

Measurement techniques: Experimental results

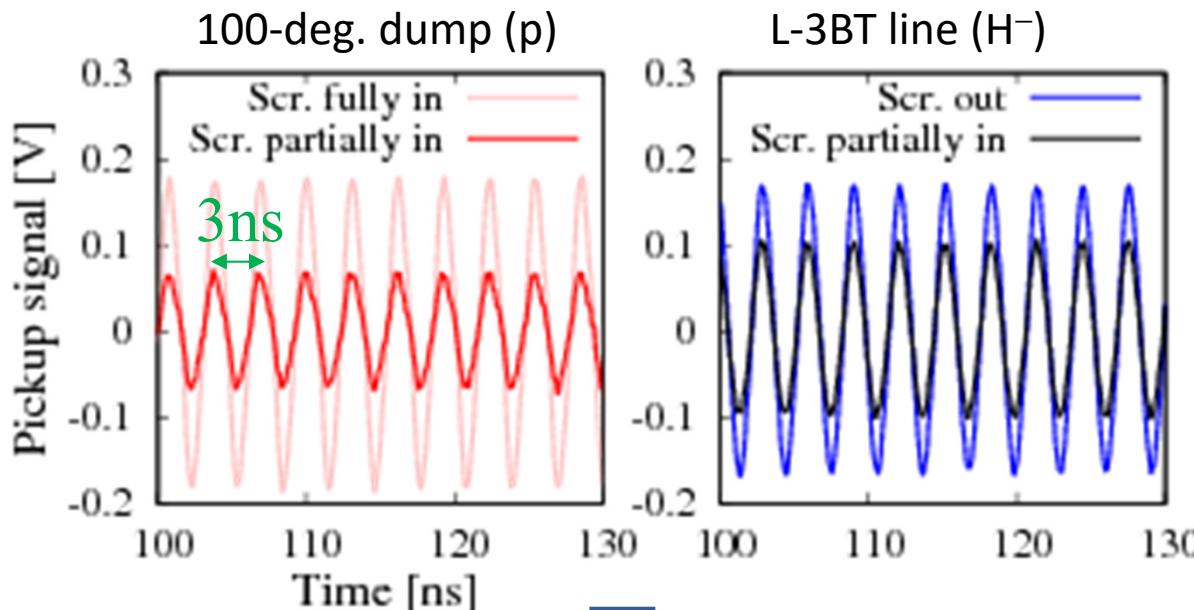

Stripping efficiency of single **medium pulse**
can easily be obtained by using FFT analysis.

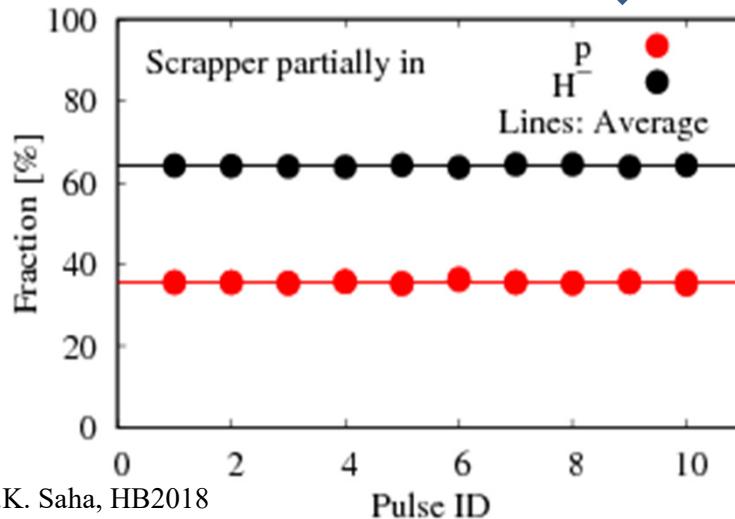

**However, we have to obtain stripping efficiency
of a single micro pulse of 324 MHz.
→ Analysis of individual micro pulse**

Analysis of individual micro pulse

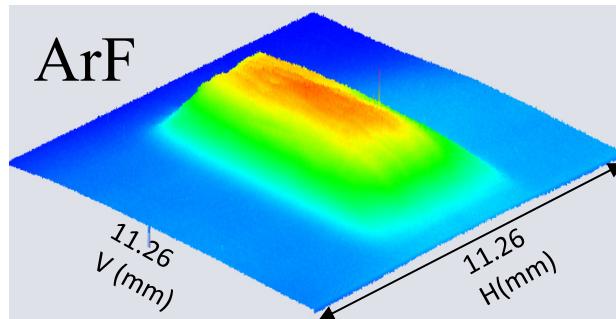

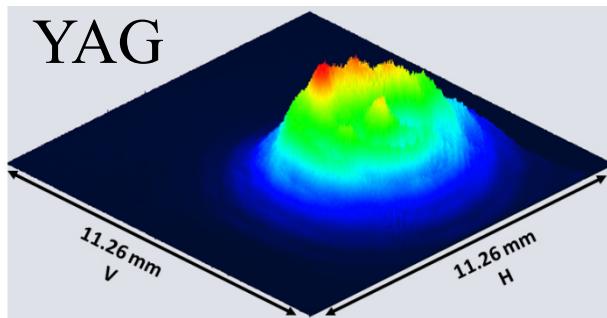

p fraction: pink to red
 H- Fraction: black to blue

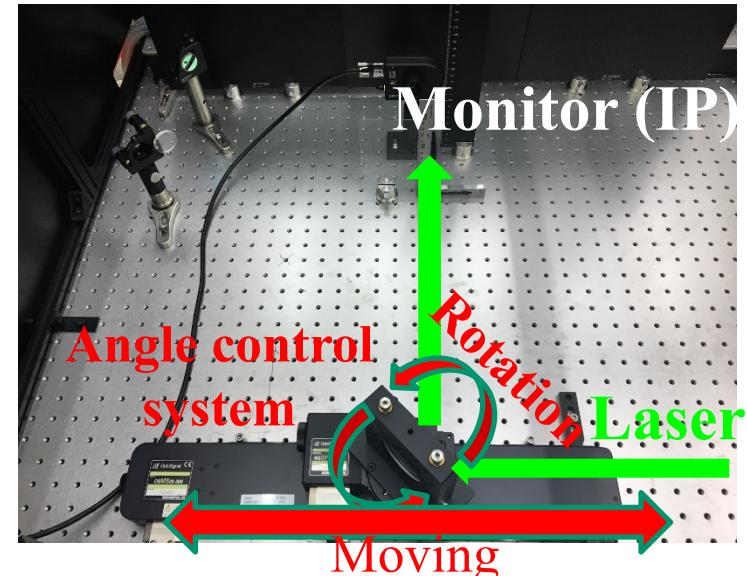

- Possible to measure stripping efficiency of individual micro pulses.
- Useful also for micro level check in long pulse/multiple pulses studies

R&D Status of the Lasers

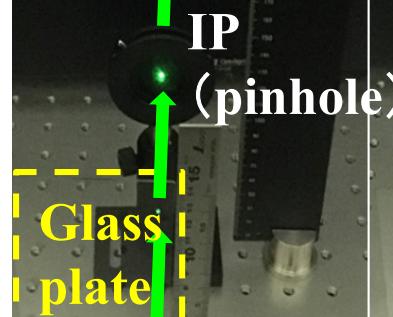

We have just started R&D of the lasers.
At present mainly for the Nd:YAG
laser up to with 0.2J.

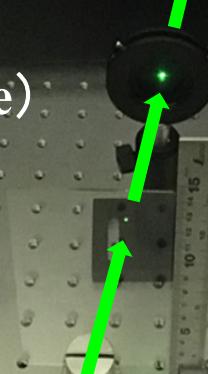

H. Harada

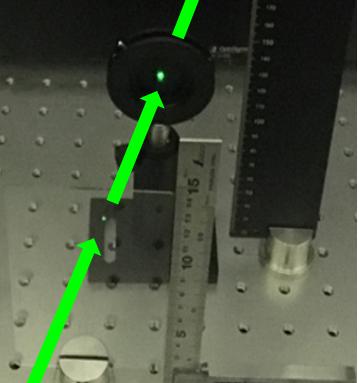

$\Delta\theta = 0$ Deg.

$\Delta\theta = 10$ Deg.

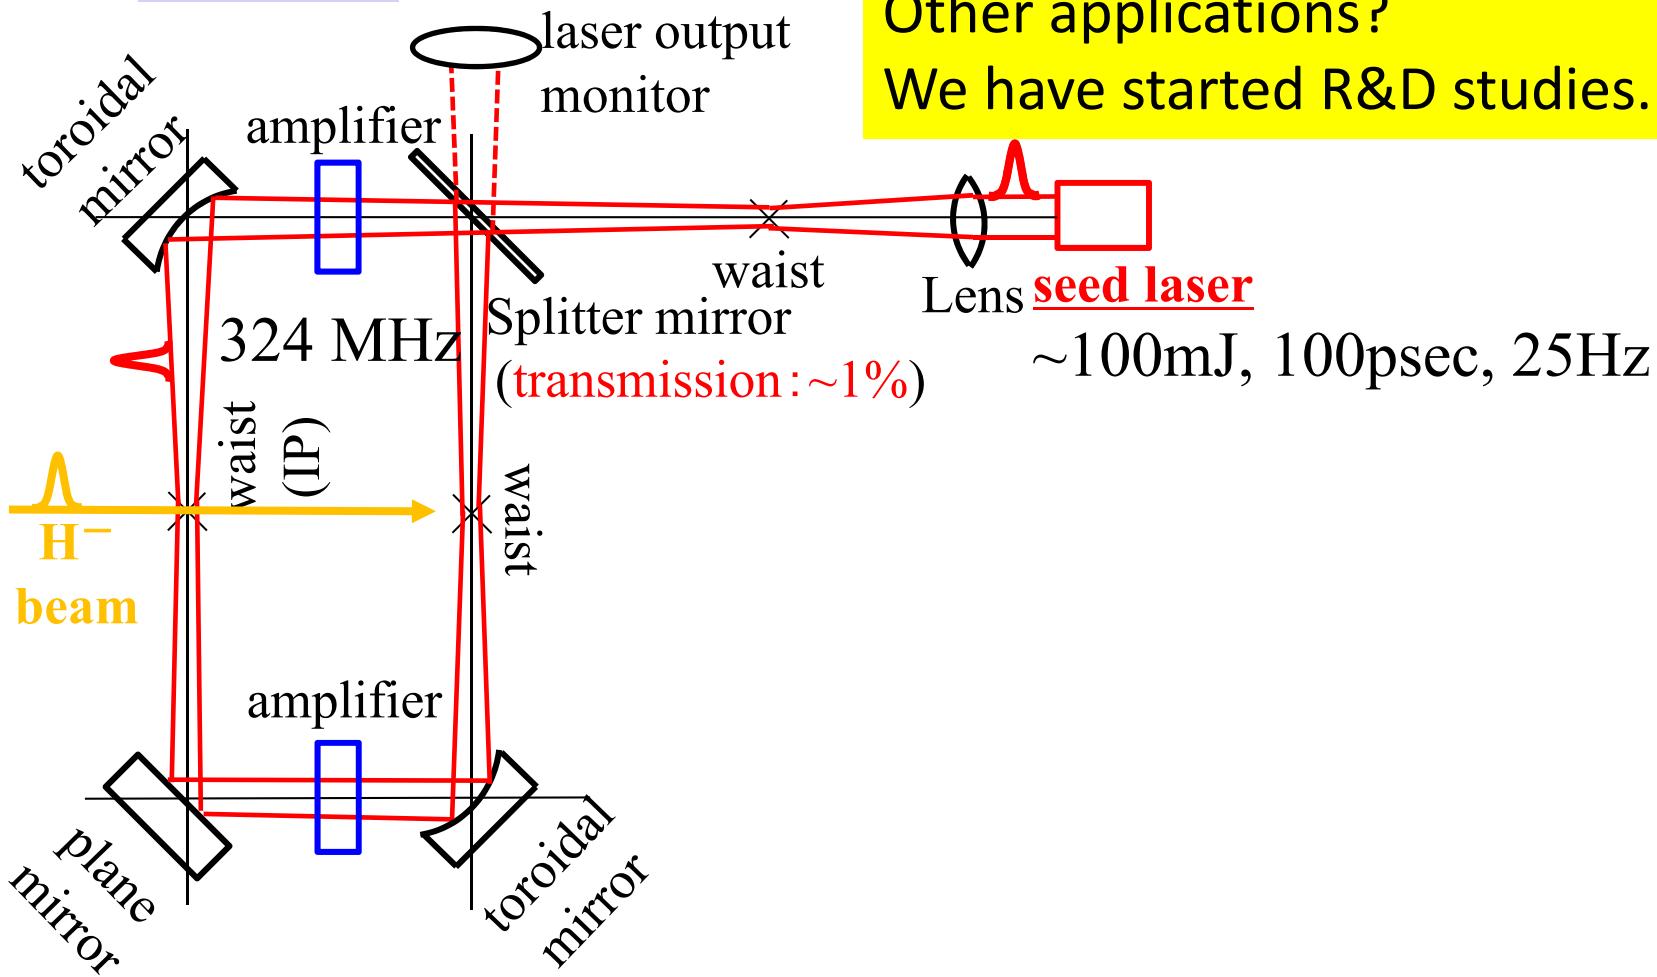

$\Delta\theta = 15$ Deg.

Angle control and optimization. Applicable for laser λ_0 change

How to cover 10^5 micro pulses (0.5 ms) for practical application?

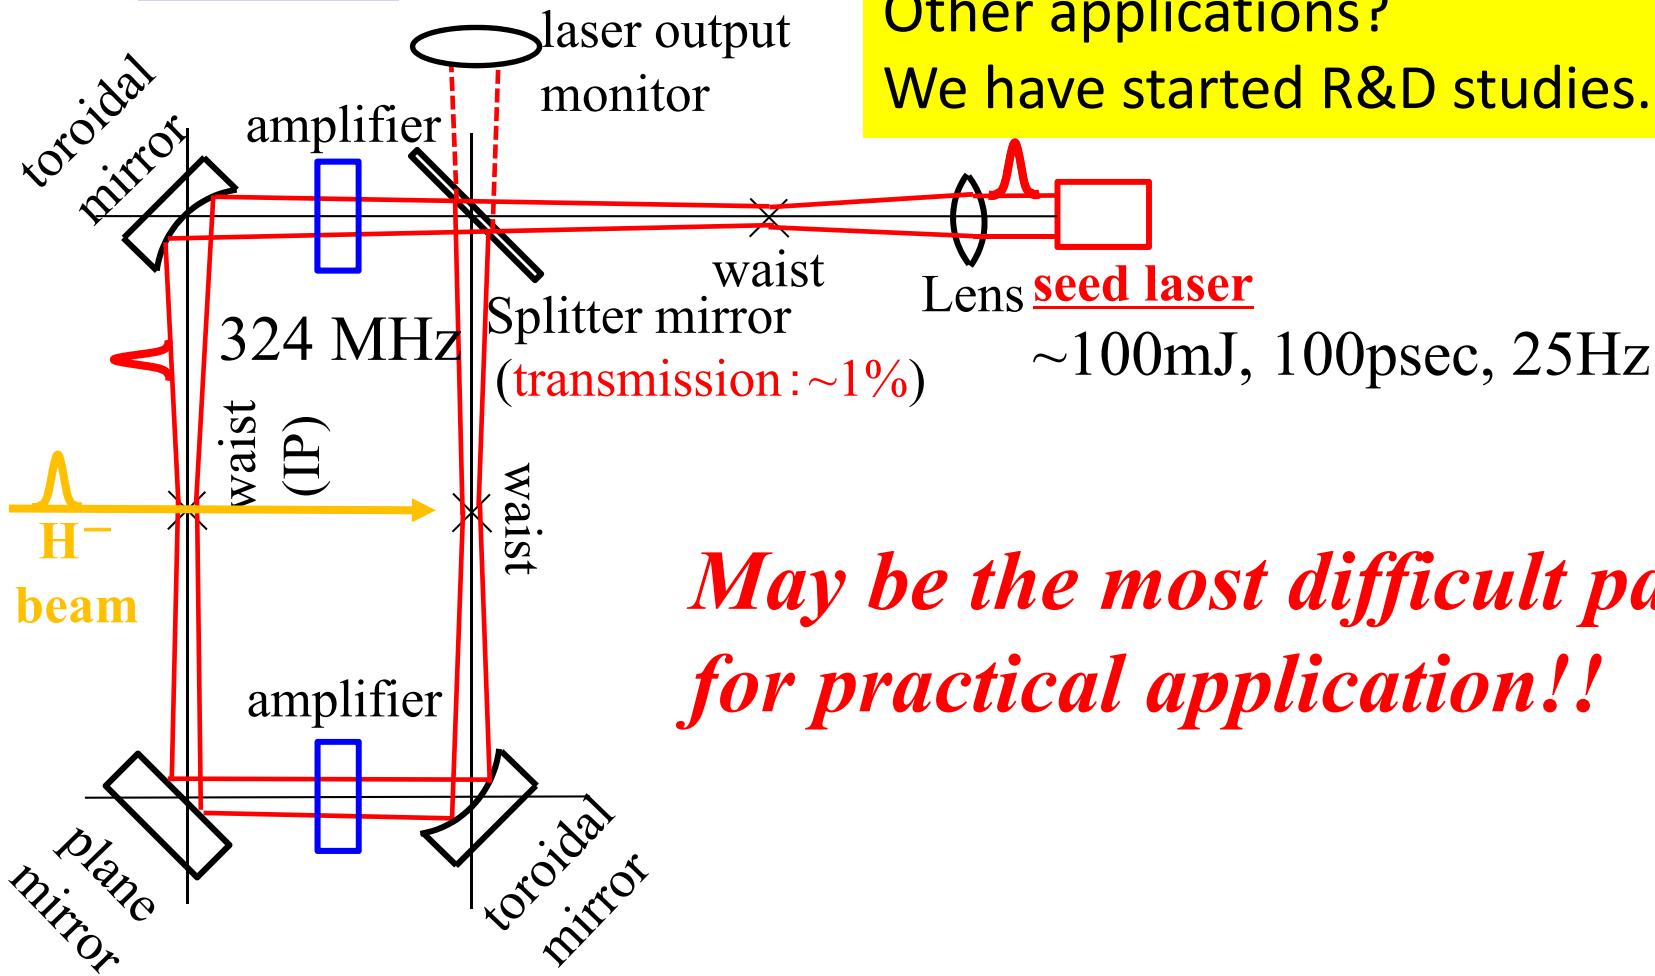

H. Harada

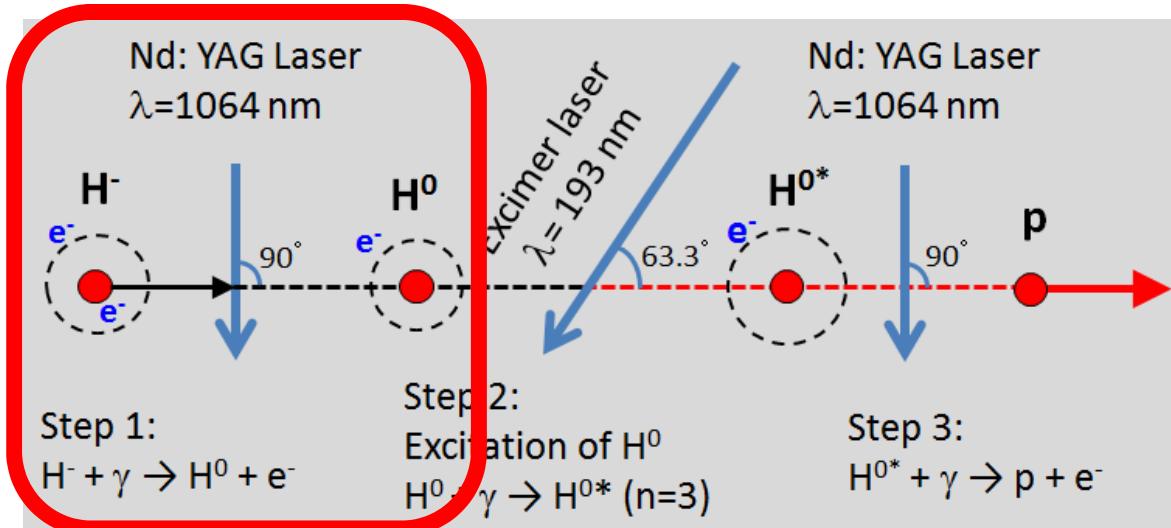

Laser storage ring ? (Y. Yamane)
Other applications?
We have started R&D studies.

How to cover 10^5 micro pulses (0.5 ms) for practical application?

H. Harada

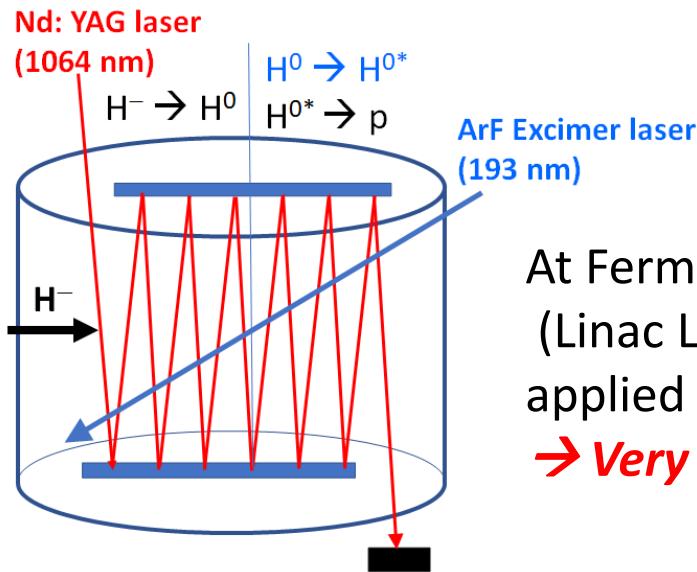

Tentative schedule, steps

- ★ The H^- neutralization study first. JFY 2018 goal.
- ★ Full scale experiment, POP demonstration: JFY 2019
- ★ Setting/placing the laser station for the POP demonstration is one big issue.

Application of 2 mirror cavity (like Fermilab) for reducing individual laser pulse energy

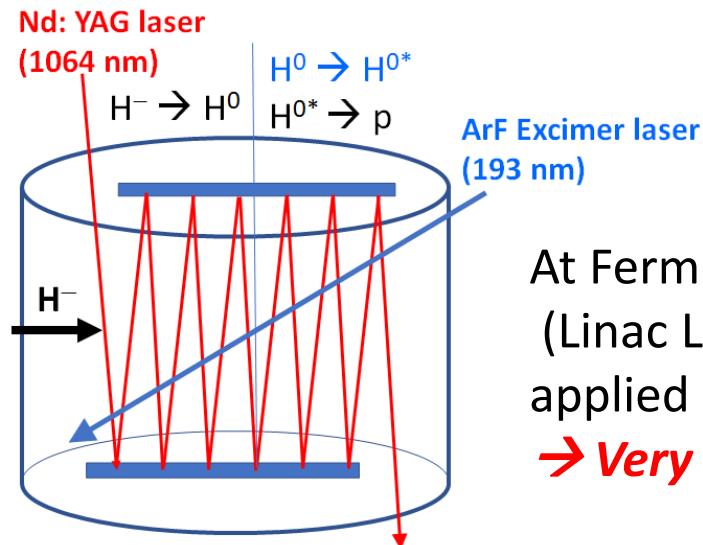

David E. Johnson, Fermilab
Private communication

At Fermilab, 2 mirror cavity system also called zigzag cavity (Linac Laser Notcher) has been developed and successfully applied for the routine operation.

→ **Very efficient to reduce the laser pulse energy.**

We made collaboration with Fermilab for the “Laser manipulations of H- beams”

Summary and outlook

- Preparation for a POP demonstration of 400 MeV H⁻ stripping to proton by using only lasers at J-PARC is in progress.
- Laser R&D studies, H⁻ beam manipulations, numerical simulations are under progress.
- A single micro pulse (100 ps) is expected to stripped with 90% eff.
- Measurement technique for one micro pulse has been established.
- Laser storage ring/other applications should be developed to cover the whole injection period.
- **The H⁻ neuralization study in JFY 2018. POP demonstration in 2019.**

Application of Fermilab 2 mirror cavity can be considered to reduce individual laser pulse energy.
