

Cédric Charrondiere, Eric Chevallay, Thomas Zilliox, CERN, Geneva, Switzerland

FABRICATION OF THE PHOTOCATHODE:

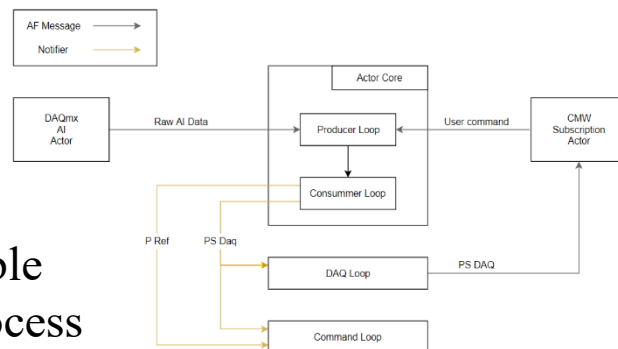

- Coating a substrate, the Cu photocathode plug, with a mixture of alkali metals and another element, tellurium or antimony.
- The cathode is illuminated with a laser.
- A photoemission reaction occurs and produces an electron current, collected and measured to quantify the cathode's performance.
- The goal is to maximize the photo-current and the quantum efficiency of the cathode.

EQUIPMENT USED

- Real-Time embedded system to control each device deterministically.

CHALLENGES

- results not easily reproducible
 - From R&D to industrial process
 - Final result affected by many parameters
 - Requires good knowledge and control of each parameter
 - Handmade power supply requires dedicated PID
-
- ```

 PSDAQ --> DAQLoop[DAQ Loop]
 PSDAQ --> CommandLoop[Command Loop]
 CommandLoop --> DAQLoop
 DAQLoop --> PSDAQ

```

## RESULTS

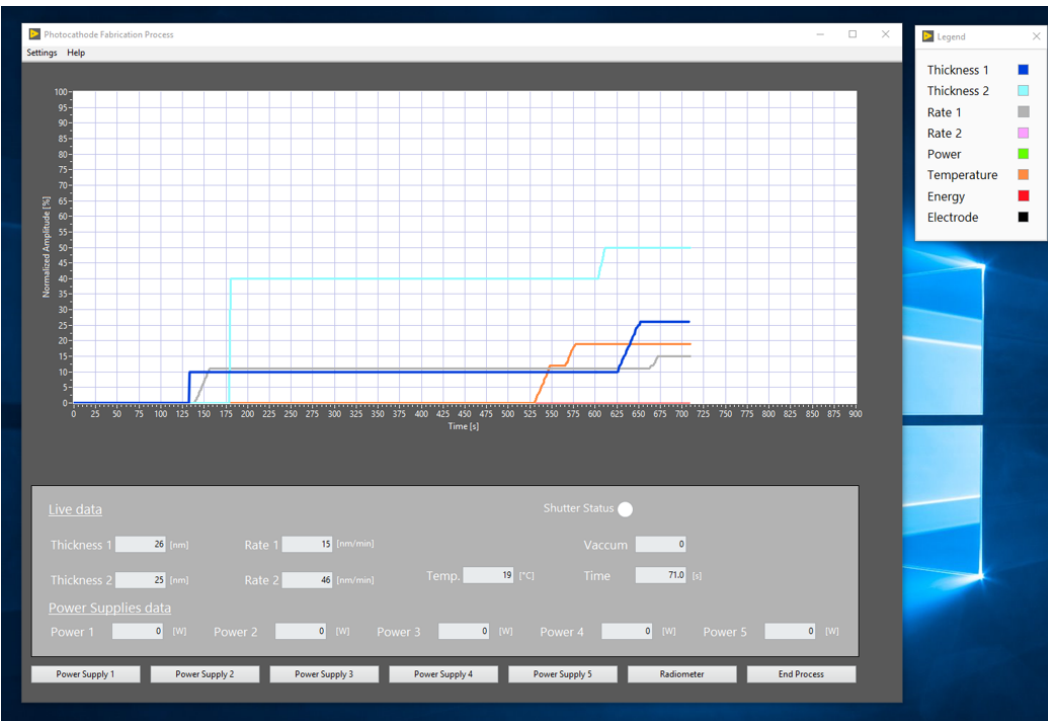

- Expert knowledge allows to obtain quantum efficiency greater than 20%
  - PXI provides flexible and deterministic solution
- Co-Deposition Photocathodes Production at the CERN Photoemission Laboratory  
from ~mid 2001 to 2021  
(Not included 8 evaporations for Daresbury Collaboration in 2020 and 2021)

Laser Wavelength: Cu<sub>2</sub>Te λ = 366 nm / Cs<sub>2</sub>Te λ = 532 nm / K<sub>2</sub>Cs<sub>2</sub>Sb λ = 532 nm

## FABRICATION OF THE PHOTOCATHODE:

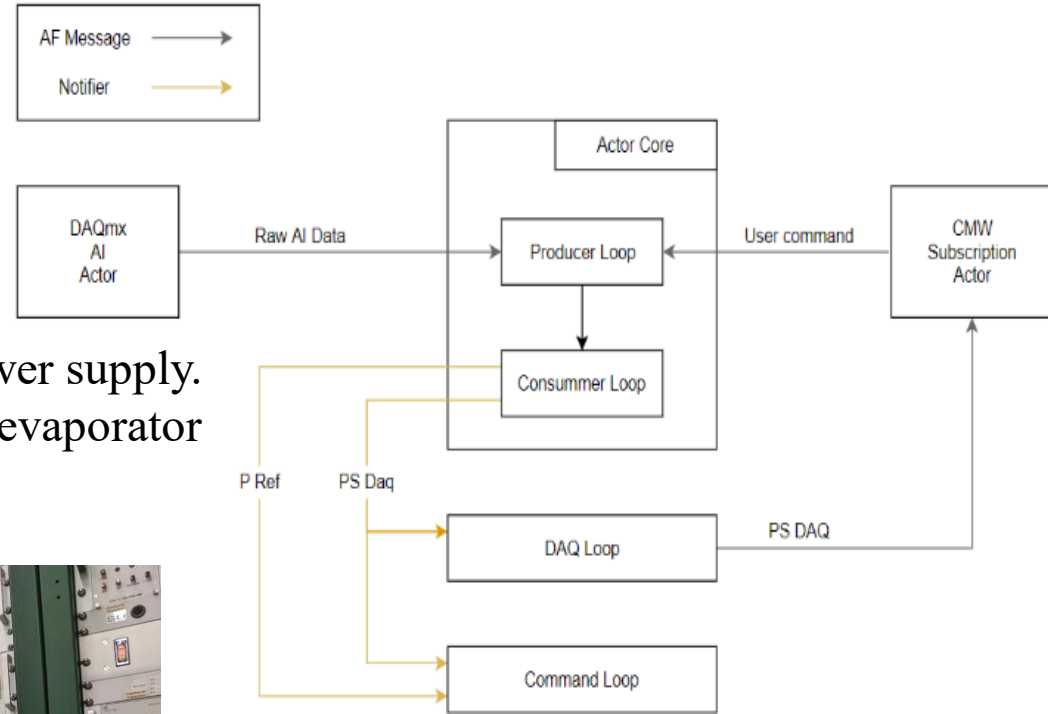

- Coating a substrate, the Cu photocathode plug, with a mixture of alkali metals and another element, tellurium or antimony.
- The cathode is illuminated with a laser.
- A photoemission reaction occurs and produces an electron current, collected and measured to quantify the cathode's performance.
- The goal is to maximize the photo-current and the quantum efficiency of the cathode.

In order to optimize the process, the system should be able to control several power supplies used to heat the evaporators and monitors the applied electrical power, temperature, laser's energy, intensity produced by the photoelectron current, thickness of the coatings and vacuum pressure.

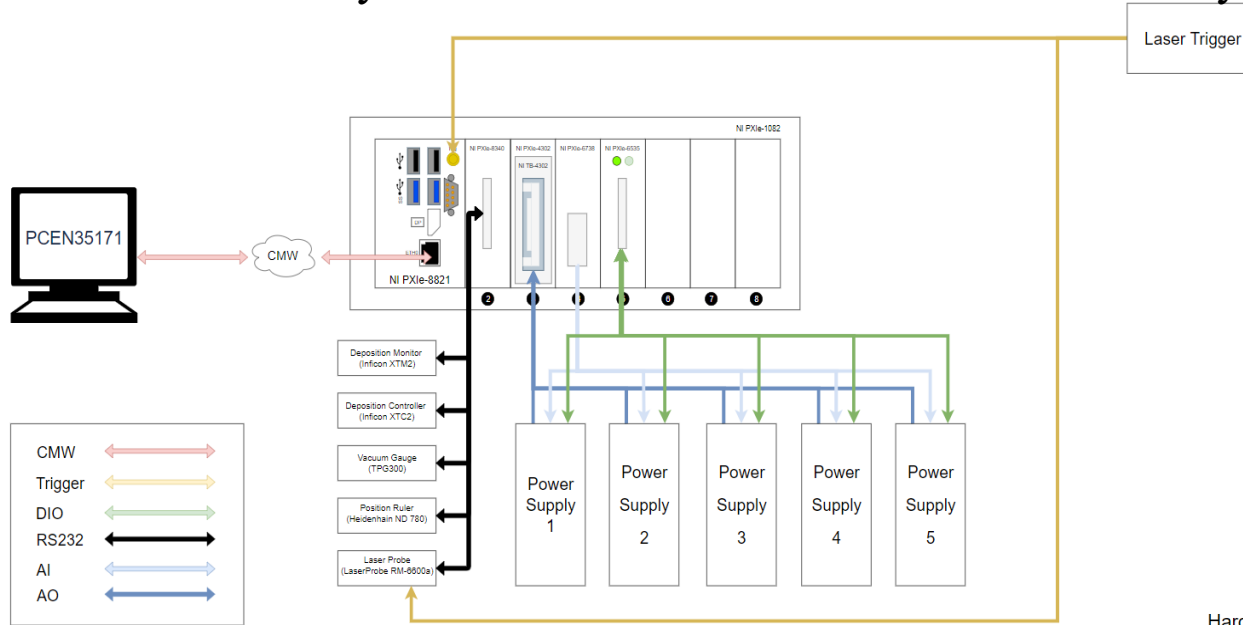

# CHALLENGES

- results not easily reproducible
- From R&D to industrial process
- Final result affected by many parameters
- Requires good knowledge and control of each parameter
  - Deposition Flow Rate of Cs or Te (called Stoichiometric Ratio Control)
  - Cesium availability in the evaporator
  - Vacuum Quality
  - Temperature (Alkalic Antimony Cathode only)
  - Evaporators mechanical positioning (ruler)
- Handmade power supply requires dedicated PID
  - power supplies are controlled in power.
  - In the hardware, only the current parameter is controlled at the power supply.
  - The voltage of the evaporator is used to compute the power of the evaporator
  - $P_{Evaporator} = U_{Evaporator} * I_{Power Supply}$

# EQUIPMENT USED

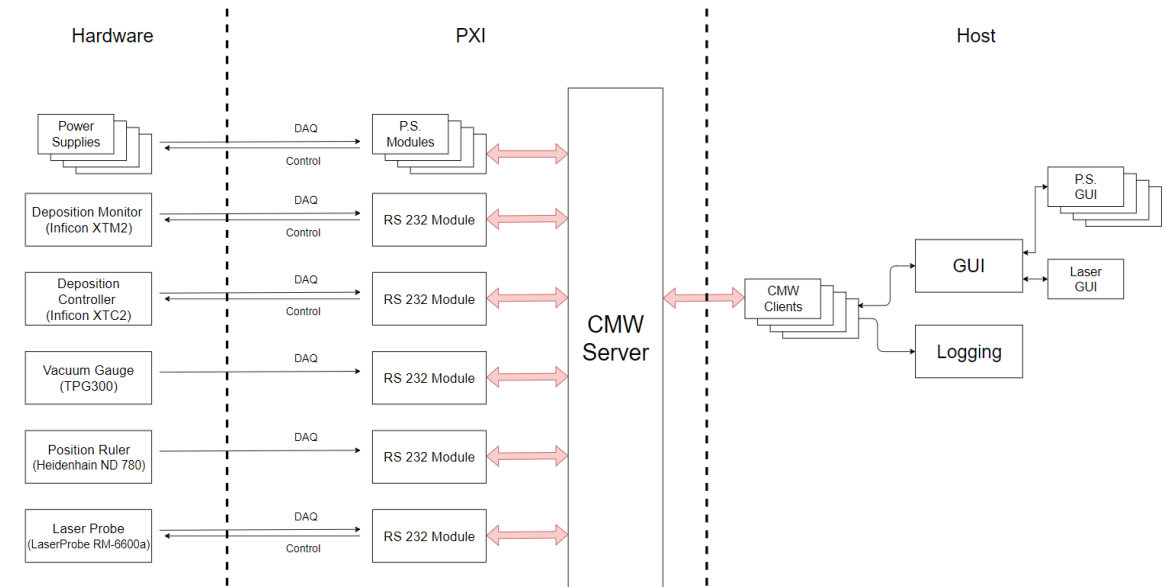

Real-Time embedded system to control each device deterministically.

The readings of the different devices are made at 4 Hz. 10 to 20 seconds are needed to get a proper deposition, and within this time we can pass from a good to a bad cathode. A good quantity of matter is needed to maximize the quantum efficiency (QE).

$$QE = K \frac{LaserEnergy}{U_{Electrode}}$$

The software is implemented using the Actor Framework, which abstracts the communication between the different modules, thereby increasing development efficiency. This framework is object-oriented, which allows us to add several layers of abstraction.

Standard 3 tiers design

## RESULTS

- The increasing knowledge of the expert allows to obtain quantum efficiency greater than 20%
- PXI provides flexible and deterministic solution
