Abstract

Flerov Laboratory of Nuclear Reaction of Joint Institute for Nuclear Research carries out the works under creating of FLNR JINR Irradiation Facility based on the cyclotron DC140. The DC140 cyclotron is intended for acceleration of heavy ions with mass-to-charge ratio A/Z within interval from 5 to 5.5 up to two fixed energies 2.124 and 4.8 MeV per unit mass. The intensity of the accelerated ions will be about 1 pmcA for light ions (A<86) and about 0.1 pmcA for heavier ions (A>132). The beam transport system has three lines: for SEE testing of microchip, for production of track membranes and for solving of applied physics problems. The design and simulation of the beam transport system from cyclotron is presented in this report. The beam focusing in the beam lines is provided by set of quadrupole lenses. The beam diagnostics system consists of the Faraday caps, luminophores and the magnetic scanning system.
INTRODUCTION

Flerov Laboratory of Nuclear Reaction of Joint Institute for Nuclear Research continues the works under the creating of Irradiation Facility based on the DC140 cyclotron [1]. Utilization efficiency of the accelerator is determined in many respects by quality of the transportation system for the extracted ions. Widely branched system of the beam lines allows one to carry out numerous investigations.

The irradiation facility will be used for Single Event Effect (SEE) testing of microchips by means of ion beams with energy of 4.8 MeV per unit mass and having mass-to-charge ratio $A/Z$ in the range from 5.0 to 5.5.

Besides the research works on radiation physics, radiation resistance of materials and the production of track membranes will be carrying out by using the ion beams with energy of about 2.124 MeV per unit mass and $A/Z$ ratio in the range from 7.577 to 8.25.

This work is devoted to the further design of the beam lines #1 and #2 for transportation of the extracted heavy ions from the cyclotron to physical targets.
BEAM LINE #1

Layout of the beam line #1 for heavy ion transportation is shown in Fig. 1. The common part of all beam lines lies from the end of the TCMH magnet (horizontal steering magnet at the extraction point) to the bending magnet (TM1) input (the beam line 0). The beam tracing to the TM1 input is carried out by means of the doublet T0Q1÷T0Q2.

Figure 1: Layout of the beam lines for heavy ion transportation
**BEAM LINE #1**

When working with the channel #1, the TM1 is switched on, it turns the ion beam at the angle of 450. There are one doublet consisting of identical standard quadrupoles (besides Q3-Q4, see Fig. 2) behind the bending magnet in the new circuit of this beam line. The total length of this version of the beam line #1 is ~ 16.281 m.

It is supposed that quadrupoles with the following parameters will be used in the beam lines: the effective length $l_{\text{eff}} = 35$ cm; aperture diameter is $D = 11$ cm; distance between the quadrupole centres in the doublets $\Delta = 58$ cm; the maximum gradient is $G_{\text{max}} = 6.0$ T/m.

The beam line #1 is designed to work with Single Event Effect (SEE) testing of microchips. New scheme of the beam line #1 is shown in Fig. 2.

**Figure 2:** New scheme of the beam line #1. Here Q1-4 are quadrupoles, TM1 is the bending magnet, T is a target.
CALCULATION RESULTS 1

Calculations of the extracted ion beam tracing were carried out with the help of TRANSPORT [2] for the ion beam parameters given in Table 1 [3].

The following designations are used in Table 1. $W$ is the ion beam kinetic energy, $\alpha_x$, $\beta_x$, $\alpha_y$, $\beta_y$ are Twiss parameters, $\varepsilon_{x,y}$ are the RMS values of horizontal and vertical emittances, $D_x$ and $D_{x}'$ are the values of the horizontal dispersion functions and their derivatives. $\Delta p/p$ is the relative spread of ion momentums.

CALCULATION RESULTS 1

In the carried out calculations one took into account the influence of the initial ion longitudinal momentum spread. For that, one calculated the behaviour of the dispersion function $D_x$ along the beam trajectory and took into account contribution of the initial ion momentum spread to the behaviour of the horizontal beam dimension.

Quadrupole gradients in the beam lines were chosen so that the beam diameter on the target to be equal to 6.8 cm (4$\sigma$) and $D_x = 0$.

As an example of the calculation results, the dependences of the horizontal $a_x$ and $a_y$ vertical ion beam half dimensions (2$\sigma$) versus the beam line length for the beam line #1 are shown in Fig. 3 ($^{209}$Bi$^{38+}$). The dispersion function $D_x$, $D_y$ is presented in Fig. 4.

BEAM LINE #2

The beam line #2 is designed for research works on radiation physics, radiation resistance of materials.

When working with the channel #2, the TM1 is switched off. There are one doublet consisting of identical standard quadrupoles (besides Q3-Q4, see Fig. 5) and bending magnet TM2 behind the bending magnet TM1 in the new circuit of this beam line. The bending magnet TM2 turns the ion beam at the angle of 45°. The total length of this version of the beam line #2 is ~ 12.803 m. Scheme of the beam line #2 is shown in Fig. 5.

CALCULATION RESULTS 2

Calculations of transportation of the beam line was carried out for 4 ion beams: $^{40}$Ar$^{8+}$, $^{209}$Bi$^{38+}$ (the initial parameters in Table 1) and $^{197}$Au$^{26+}$, $^{132}$Xe$^{16+}$ (the initial parameters in Table 2) [3]. Quadrupole gradients in the beam lines were chosen so that the beam diameter on the target to be equal to 2 cm (4σ).

CALCULATION RESULTS 2

The calculation results, the dependences of the horizontal and vertical ion beam half dimensions versus $l$ for the beam line #2 are shown in Fig. 6,8 ($^{197}\text{Au}^{26+}$, $^{132}\text{Xe}^{16+}$). The appropriate dispersion function $D_x(l)$ is presented in Fig. 7,9.

CONCLUSION
The calculations of tracing ion beams of the cyclotron DC140 were carried out for all considered ion beams in both beam lines. In the beam line 1 the beam diameter of 6.8 cm (4σ) and the value of $D_x = 0$ were obtained on the target. In the beam line 2 the beam diameter of 2 cm (4σ) and the value of $D_x < 0.3\%$ were obtained on the target. The required gradients in the quadrupoles have the values not exceeding their limit in all cases considered in both beam lines.
