Relevance

For accelerators based on CHIP structures, two directions are relevant. With the maximum miniaturization of devices - obtaining the maximum efficiency of acceleration and on this basis - their optimization for the production of this type of accelerators for consumer and research purposes.

| | |
|---------------------------------|-------------|
| Chip-structure damage threshold | 30 GV/m |
| Max. achievable gradient | 10 GeV/m |
| Drive period | ~ 5 fs |

Fields of promising application: medicine, materials science, biochemistry, in physics - obtaining ultrashort electron bunches of the order of 5-10 fs.

Modeling subject

Experiments were carried out to simulate acceleration processes on periodic structures of various profiles

1 – Rectangular,

2 – Cylindrical,

3 – Grooves,

4 – Sinusoidal,

5 – Triangular

Structure period $\lambda_p = 800 \text{ nm}$;

Pillar height $h = \lambda_p / 2$;

Structure length $L = 16 \mu\text{m}$

1) when they are excited by
a plane wave -

$$\tilde{E}_p = E_p \exp \left[- \left(\frac{x}{w_1} \right)^2 - 2 \ln(2) \left(\frac{t}{\tau_p} \right)^2 \right]$$

2) and Gaussian wave – $E(r, z, t) = E_p \frac{w_0}{w(z)} \exp \left[- \frac{r^2}{w^2(z)} \right] \exp \left[- 2 \ln(2) \frac{(z - ct)^2}{c^2 \tau_0^2} \right]$

$$\times \Re \left\{ \exp \left[i \omega_0 t - i k_0 z - i k_0 \frac{r^2}{2R(z)} + i \psi_g(z) \right] \right\}$$

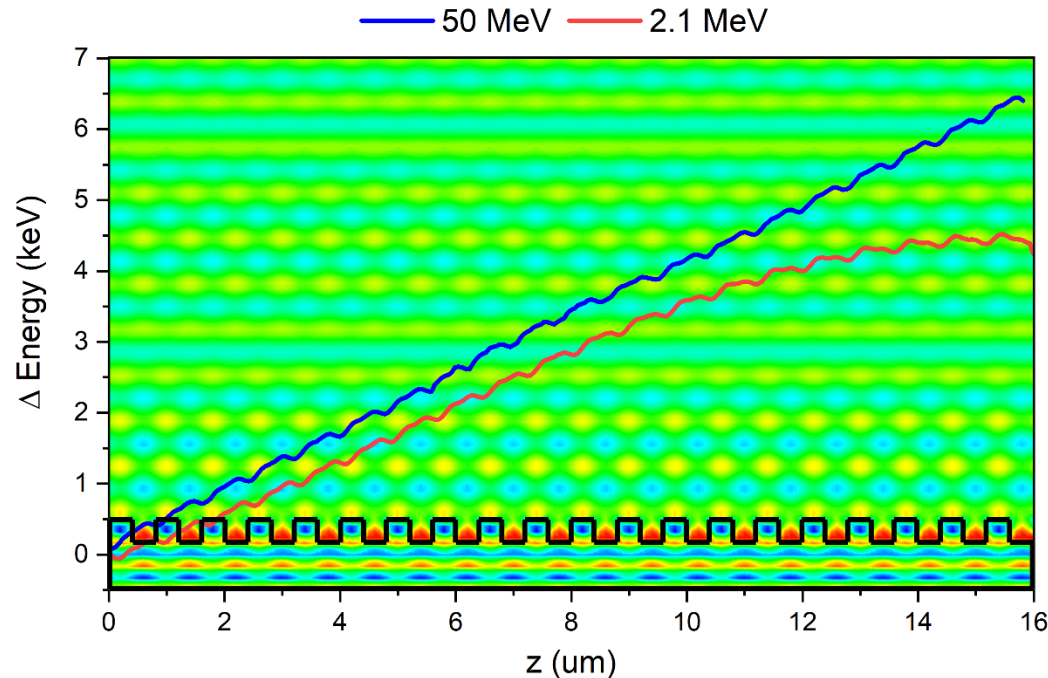

Where E_p - electric field amplitude, w_0 - laser waist at $z = 0$, τ_0 - laser pulse duration, c - speed of light, $k_0 = 2\pi / \lambda_0$ and $\omega_0 = ck_0$ – wave number and angular frequency of a laser beam with a wavelength λ_0 , $w(z)$ – beam waist on the z axis, $R(z)$ – the radius of curvature of the wave front, $\psi_g(z)$ – Phase Shift Gouy

Average energy gain for a rectangular structure

The height of the flight of electron beam over the structure $y = 200$ nm,
 $E_p = 10^9$ V/m

Plane wave

Gauss wave

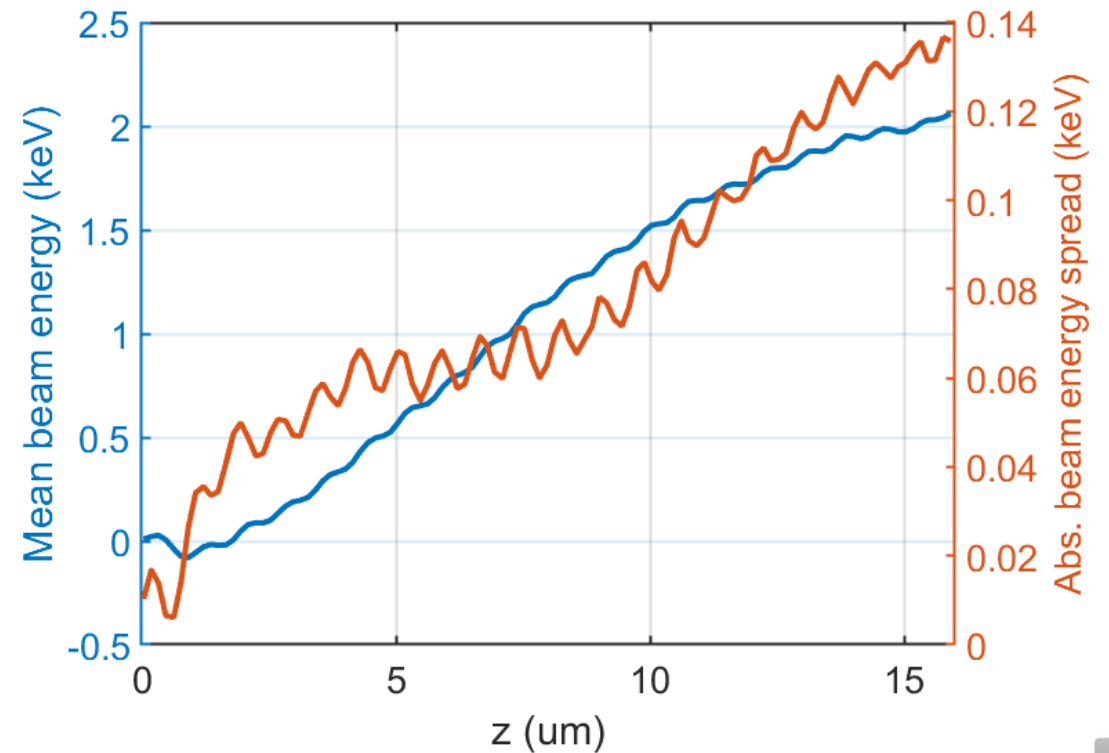

Average gain and spread of electron energy for a rectangular structure

$$y = 200 \text{ nm}, E_p = 10^9 \text{ V/m}, E_0 = 2.1 \text{ MeV}$$

Plane wave

Gauss wave

Average gain and spread of electron energy for a rectangular structure

$$y = 200 \text{ nm}, E_p = 10^9 \text{ V/m}, E_0 = 50 \text{ MeV}$$

Plane wave

Gauss wave

Average increase in electron energy for different beam heights over a rectangular structure

$$E_0 = 2.1 \text{ MeV}$$

Plane wave

Gauss wave

Average increase in electron energy for different beam heights over a rectangular structure

$$E_0 = 50 \text{ MeV}$$

Conclusions

- As expected, when the parameters in the simulation approached the real experiment, and the excitation of the structure by a Gaussian wave gave lower acceleration rates than when simulating the excitation of the structure by a plane wave.
- Comparative analysis shows that in almost all cases the rectangular structure shows the best result, at $y = 200$ for electrons with an energy of 50 MeV and excitation of the structure by a Gaussian wave, the cylindrical structure turned out to be 14% worse, the grooves and sinusoidal showed deterioration by 24% and 27% accordingly, the triangular one showed the worst result - acceleration is 59% lower.
- Commercially available diffraction gratings (for example, grooves) also provide a fairly high acceleration rate and can be used for experiments.

Thanks for attention!
