Abstract

The GM/CA-developed, quad-mini-beam collimator [1, 2, 3], advanced rastering and vector data-collection software tools [4], have enabled successful data collection on some of the most challenging problems in structural biology. This is especially true for membrane-protein crystals grown in lipidic cubic phase, where crystals are typically small, fragile, and “invisible” when cryo-cooled. There are two main sources of X-ray scattering (besides the sample) that reach the detector, contribute to background and limit data resolution. These are scattering within the collimator that escapes the exit aperture and air-scattering of the direct beam before it terminates in the beam-stop. Scattering from the collimator can be reduced by decreasing the exit aperture size. A quad mini-beam collimator was built consisting of 5-, 10-, 20- and 150 μm beam defining apertures with 50-, 70-, 100- and 300 μm exit apertures, respectively. Previous collimators were positioned in the X-ray beam by two motorized translational motions and two manual angular adjustments via a kinematic mount. The individual beams were selected by recalling stored translational positions. The pitch and yaw angular adjustments were manually pre-adjusted to one optimal position for all four apertures (Figure 1). An active beam stop of 1.0 mm diameter is typically positioned about 35 mm downstream of the sample. A prototype collimator with 5 μm beam defining and 150 μm exit aperture was developed for scanning X-ray micro diffraction studies of tissue architecture. This collimator in combination with a 0.5 mm beam stop resulted in a 30% background reduction, prompting us to develop dual pin-hole collimators for reduced background.

Figure 1: Close up of the Quad collimating system installed at the beamline end station. Two high resolution micro translation stages are combined to form an XY system for the collimators alignment. The travel range is 15 mm for both horizontal and vertical. The design resolution is 0.007 μm and the repeatability is 0.1 μm. The whole system stability is +/- 0.1 μm.

INTRODUCTION

Since 2007, GM/CA has provided micro-diffraction capabilities at both 23-IDD and 23-IDB beamlines through versatile collimator systems. A robust, monolithic quad-collimator provided user-selectable beam sizes of 5, 10, 20 μm or “full beam” (~25 x ~75 μm FWHM). These quad collimators were positioned in the X-ray beam by two motorized translational motions and two manual angular adjustments via a kinematic mount. The individual beams were selected by recalling stored translational positions. The pitch and yaw angular adjustments were manually pre-adjusted to one optimal position for all four apertures (Figure 1).

DUAL PIN-HOLE COLLIMATOR

Design of Dual Pinhole Collimator

The dual pinhole collimator design significantly reduces the X-ray scattering that escapes the collimator, Figure 2. The collimator assembly has a steel scatter guard body that hosts an entrance and exit sub-assembly. Both sub-assemblies consist of a steel cap and a Platinum pinhole...
aperture. The pinhole of the entrance sub-assembly acts as the X-ray beam defining aperture while the pinhole of the exit sub-assembly captures the scatter from the beam defining aperture and air scatter within the collimator body. The steel cap upstream of the beam defining aperture prevents back scatter from escaping the collimator body, while the steel cap down-stream of the exit aperture further reduces the scatter escaping the collimator.

Quad Mini-beam Collimator with Dual Pinhole

The dual pinhole concept was incorporated into a quad, uni-body collimator, Figure 3. The collimator includes four sets of pinholes. Three sets are for mini-beams and one trims the full beam in the horizontal direction to allow a 0.5 mm diameter beamstop to be used. The history of the development of the GMCA quad collimator is illustrated in Figure 4.

COLLIMATOR POSITIONING WITH MOTORIZED PITCH AND YAW ADJUSTER

Collimators with small exit apertures require not only X and Y translations to select a particular beam size, but also adjustment of the pitch and yaw angles to center the exit aperture. This necessitated developing a new collimator positioning system with motorized pitch and yaw adjustments, a 3-D model of the collimator positioning system is shown in Figure 5 and two prototype quad collimator assemblies have been built and installed (Figure 6). It consists of: three frames, four C-flex bearings, two actuators and two high precision stages. The two pairs of commercial flex bearings function as a universal joint. The motions of this universal joint are manipulated about the vertical and horizontal axes by two high precision SmarAct actuator stages. Four dual- pinhole collimators are mounted on a block that in turn is mounted on the internal frame. The block’s center coincides with the intersection of the two rotation axes resulting in pitch andYaw motions. The novelty of the new mechanical design is the compactness and positional stability of the structure.

Figure 5: Schematic diagram of the assembled new dual pinhole mini-beam collimator with motorized pitch and yaw adjuster. Backscatter guards with pinholes are inserted in the square-shaped scatter guard. The exit holes are smaller for mini beams. The pinhole selects the central part of the focused beam.
MINI-BEAM COLLIMATOR WITH SMALL EXIT APERTURES PROVIDES LOWER BACKGROUND

A quad mini-beam collimator was built consisting of 5-, 10-, 20- and 150 μm beam defining apertures with 50-, 70-, 100- and 300 μm exit apertures, respectively. Background diffraction patterns (no sample) were systematically recorded for various aperture combinations, and the scattered intensity was radially integrated from the origin to the edge of the pattern, and normalized by the number of pixels.
