Abstract. The plasma lens can carry out not only sharp focusing of ions beam. Plasma lens provides formation of hollow beams of ions. Application of the several plasma lenses allow to get a conic and a cylindrical beams. The plasma lens can be used for obtaining a beams with homogeneous spatial distribution.

By measuring the distribution of ions in the beam at the input and output lenses can determine the current distribution in the pinch through the numerical calculation.
Ion focusing in a plasma lens

Advantages of plasma lens:
- focusing power is proportional to the magnetic field strength;
- there is no limit for the magnetic field magnitude connected with saturation;
- charge neutralization of ion beam into the plasma lens;

\[ F = Z e v_z B_\phi(r) \]
\[ B = \frac{\mu_0}{2} j r \]
\[ d_{\text{min}} \sim \varepsilon I^{1/2} \]

$T = 0.5 \mu s$  $T = 1.6 \mu s$  $T = 8.5 \mu s$
CONCLUSION

The plasma lens can carry out not only sharp focusing of ions beam with considerable reduction of their sizes. At those stages of the plasma discharge at which the magnetic field is nonlinear, formation of other interesting configurations of beams is possible.

The plasma lens provides formation of hollow beams of ions in a wide range of parameters that allows to consider it as a possible variant of a terminal lens for realization of inertial thermonuclear synthesis.

The plasma lens can be used for transformation of beams with Gaussian distribution of particles density in a beams with homogeneous spatial distribution.

Application of the several plasma lenses which are in different stages of the plasma discharge, presumes to create some nontrivial spatial configurations of ions beams.

The plasma lens represents the universal tool for investigation of plasma discharges.
